Acknowledgments

Funding for this project was provided by the Great Lakes Protection Fund through the WDNR's Division of Water, Bureau of Watershed Management, and the Land Division's Bureau of Endangered Resources. This support is gratefully acknowledged. Special thanks to Chuck Ledin for facilitating work with the Water Division.

A number of individuals conducted inventory work and provided support and technical advice to complete this project. We would like to extend our thanks to those persons listed below for their assistance. We would also like to extend our appreciation to the many private landowners who granted us permission to work on or cross their properties.

Data Management/GIS/Graphics Development:

Julie Bleser, Natural Heritage Inventory Database Manager
Terrell Hyde, Natural Heritage Inventory Assistant Zoologist

Report Coordination/Administration:

Nicole Merryfield, Contractor
Betty Les, Chief, Natural Heritage Inventory Program

Inventory Personnel: The following people conducted inventory work for this study.

Andy Clark – botany, ecology, rare flora
Eric Epstein – botany, ecology, rare flora
Gary Fewless – botany, ecology, rare flora
Mike Grimm – birds, TNC analysis of the Niagara Escarpment
Dr. Emmet Judziewicz – botany, ecology, rare flora
Kathy Kirk – terrestrial invertebrates, Hine's emerald dragonfly
Dr. Kurt Schmude and students – aquatic invertebrates
Bill Smith – terrestrial and aquatic invertebrates, rare fauna
Julie Bleser – data management

Reviewers/Advisors: The following individuals provided specific assistance in some phase of the project. We are grateful for their help and the help of many other people and organizations who contributed to the project. Roy Aiken; Tim Cashatt; Gary Casper; Matthew Christiansen; Steve Dutch; Ron Fassbender; Bob Hay; Randy Hoffman; Darcy Kind; Arnie Lindauer; Todd Miller; Dr. Jeff Nekola; Crystal Olson; Jeffrey Pritzl; Kathleen Regnier; Jim Reinartz; Maureen Rowe; Joseph Senulis; Dan Soluk; Ron Stieglitz; Elizabeth Spencer; Jim Theler; Gene Tiser; Joel Trick; Tim Vogt; Mark Walter; Curt Wilson; Kristin Westad; Mary Standish; Michelle Hefty.

INTRODUCTION

The Niagara Escarpment has emerged as a statewide critical natural resource area in recent years due to its unique geology, the presence of rare plants and animals, and growing development pressure. It is a priority study area for the Bureau of Endangered Resources and the Department of Natural Resources, as well as other regional and state agencies and private conservation organizations in Wisconsin.

This report presents the results of a study conducted during 1999-2001 to collect and compile information about the biodiversity of the Niagara Escarpment throughout its course in Wisconsin, and to identify elements of biodiversity that are most closely associated with the Escarpment. The study was undertaken by the Natural Heritage Inventory (NHI) Program of the Wisconsin Department of Natural Resources' Bureau of Endangered Resources. Work emphasized consolidation of existing data and information plus field inventory to fill in gaps and to gather more complete information on key sites.

The information provided in this report is intended to support current and future planning efforts for the Department, local planning agencies, concerned community groups, and other organizations. This compilation should provide a tool with which to evaluate the ecological significance of the Escarpment and provide background for conservation efforts and management considerations. By focusing on the Escarpment as a whole, we hope that this report provides a useful frame of reference for regional and local studies dealing with portions of this important area. We also hope that the emphasis on rare species and natural communities in this report will complement other, more general information about the area. Terms that may be unfamiliar to readers are defined in Appendix 1.

DESCRIPTION OF STUDY AREA

This report covers the seven counties that contain the majority of the Niagara Escarpment in Wisconsin. The study area includes the exposed bedrock of the Escarpment within these counties plus a 5 mile buffer on all sides (Map 1). The seven counties are Brown, Calumet, Dodge, Door, Fond du Lac, Kewaunee, and Manitowoc. Nearby outliers of exposed bedrock were excluded from the study area because of their small size and, in most cases, their non-dolomitic composition, which indicates that they are not part of the Escarpment.

ECOLOGICAL SETTING OF STUDY AREA

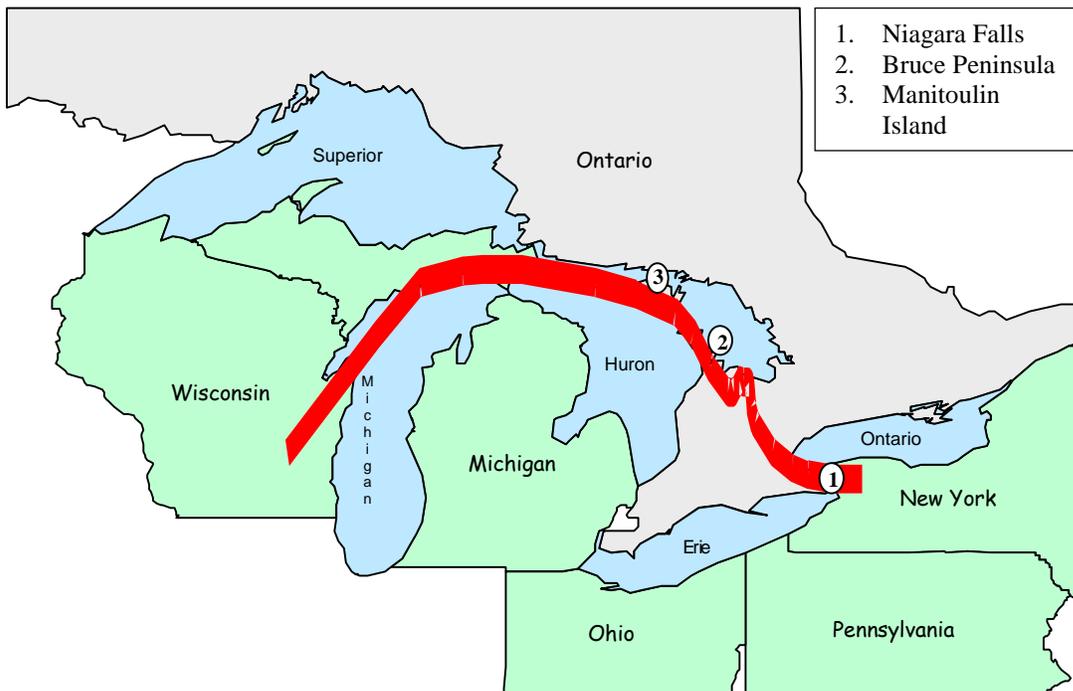

The study area falls within 3 of Wisconsin's 16 ecological landscapes, based on a system of land classification developed by the Wisconsin Department of Natural Resources. This system divides the state into ecological units based on combinations of biotic and environmental factors, which include climate, physiography, soils, hydrology, and vegetation (Map 2). The Department's system is a modification of the National Hierarchical Framework of Ecological Units (NHFEU). The 3 ecological landscapes pertinent to this study are:

1. **Northern Lake Michigan Coastal:** Lake Michigan climate influence; gently rolling to flat topography with clay and loam soils; land cover now dominated by agriculture in the south and mixed conifer-hardwood forest in the north.
2. **Central Lake Michigan Coastal:** Lake Michigan climate influence; generally flat topography with clay and silt loam soils; land cover now primarily urban and agricultural; some remnant northern hardwood forest with maple, beech, and some hemlock, plus conifer swamps, hardwood swamps, and riverine marshes.
3. **Southeast Glacial Plains:** Gently rolling to flat topography with clay or silt loam-textured soils on till plain; land cover now primarily urban and agricultural; small remnant oak openings, oak forest, tallgrass prairie, and sugar maple-basswood forest.

GEOLOGY OF THE ESCARPMENT

The Niagara Escarpment is the steep face of a 650-mile sickle-shaped cuesta (bedrock ridge) that runs from the northeastern United States south of Rochester, New York, across portions of southeastern Canada, and then southward north and west of Lake Michigan to southeastern Wisconsin (Map 3). The portion of the Escarpment occurring in Ontario Canada has been designated as a World Biosphere Reserve by the United Nations Education, Scientific and Cultural Organization (UNESCO).

Map 3. Escarpment Location in Relation to the United States and Canada.

Large area of recently exposed dolomite on point at south end of Sand Cove, September 30, 2000. Photo by Gary Fewless

The primary bedrock type is dolomite, formed from accumulated sediments of an ancient sea 405-425 million years ago during the Silurian Period of the Paleozoic Era (Paull and Paull, 1977). The Escarpment was formed over millions of years through the differential erosion of rocks of different hardness. A cap of erosion-resistant dolomite overlies weaker, more easily eroded and weathered shale rocks. Through time the soft rocks weather and erode away by the action of water, and freezing and thawing cycles. The gradual removal of the soft rocks undercuts the resistant caprock, leaving series of cliffs – the Niagara Escarpment. The Silurian dolomite is a calcareous rock unit with high concentrations of magnesium and small concentrations of iron (Corbisier et al., 2000).

In Wisconsin, the Escarpment extends for over 230 miles (Martin, 1965), from Rock Island, off the northern tip of the Door Peninsula, south to northern Waukesha and Milwaukee counties (Watermolen et al, 1997). The Escarpment is discontinuous in Wisconsin and differs in elevation and amount of exposure from one end to the other. The middle portion of the Escarpment is over 300 feet higher than the northern and southern ends (Bay-Lake Regional Planning Commission, 2001). A good example of the variability of the Escarpment is on the Door Peninsula where the Escarpment is expressed as a prominent rock face and steep west-facing scarp with cliffs reaching 150 feet in height (Map 4). The bedrock of the cuesta has a gentle eastward dip that outcrops at many locations along the Lake Michigan shore of the northern Door Peninsula as series of ledges, low cliffs, and pavements.

The role of glacial processes in shaping the Escarpment in Wisconsin is described by the Bay-Lake Regional Planning Commission (BLRPC):

Glacial processes also have impacted the escarpment greatly, controlling its expression in a variety of ways related to the direction of ice movement. For example, the glaciers may have eroded the western edge of the escarpment back five to ten miles on the north, smoothing out the irregular cliff face and removing outliers, as the ice moved parallel to it. Farther south, where the ice moved obliquely, the outline of the escarpment is more irregular. Much of the southern portion of the escarpment is partly buried by glacial deposits (BLRPC, 2001).

Areas along the Niagara Escarpment have thin soil deposits due to glacial scouring and relatively little post glacial deposition. These conditions of shallow soils lying directly over fractured bedrock make the area susceptible to groundwater contamination.

The geology of the Escarpment greatly influences its ecological attributes. One example is the presence of the karst or solution features of the bedrock that allow organic matter to accumulate. Cold air and sometimes water move through the fractured rock creating unique microhabitats, some of which mimic cold air slopes (Corbisier et al, 2000). Many highly specialized species, such as rare terrestrial snails, are found in these microhabitats and some of them may occur in few or no other locations in the world (WDNR, 2002).

LAND COVER AND LAND USE

The first systematic record of vegetation in Wisconsin occurred in the mid-1800s, when the U.S. General Land Office completed a land survey of the entire state to facilitate European settlement (Les, 1995). Vegetation maps based on these records show a diverse mosaic of natural communities, including extensive forests and wetlands, as well as fire-dependent grassland, barrens, and savanna communities. On the Door Peninsula forest dominants included sugar maple, basswood, yellow birch, beech, elm, white pine, and hemlock. From lower Green Bay south, the native vegetation was composed primarily of deciduous forest (oaks, maples, ashes, basswood), oak savanna, prairies, and wetlands.

During the last half of the nineteenth century much of the pre-settlement forest was cut and much of the land was cleared for agriculture, especially fruit orchards. Farming along the Escarpment was difficult due to the shallow soils and steep slopes, and settlement patterns were affected by the bedrock-controlled topography. The dolomite bedrock was available for foundation material or to be burned to produce lime. Today, a number of county operated or privately owned quarries supply crushed stone primarily for road base or concrete aggregate and riprap.

Current land use patterns along the Niagara Escarpment were documented in a comprehensive assessment by the Bay-Lake Regional Planning Commission (2001). The report characterized land use and cover along the Escarpment as a mix of agricultural land, woodlands, and locally concentrated developments. Land use patterns on Door Peninsula were described as follows:

Going from north to south the woodlands decrease in size and abundance with a natural break just north of Sturgeon Bay. South of Sturgeon Bay, land use is typically agricultural with scattered wood lots and development. Large concentrations of development are in and around Sturgeon Bay, Green Bay, east and northeast of Fond du Lac, and smaller areas of development are located in the villages of Ephraim, Sister Bay, and Egg Harbor.... The majority of the shoreline in Brown and Kewaunee counties is also developed, mostly with residential uses (BLRPC, 2001).

Shoreline near the Escarpment has been extensively developed near the cities of Green Bay, Fond du Lac, and Sturgeon Bay, as well as at many areas in between these cities.

The development along the shoreline from Green Bay to Sturgeon Bay can be viewed as a timeline of development trends. Development that took place in Green Bay and the town of Scott is now starting to become apparent in Red River and Union. The same pattern is occurring north from Fond du Lac along the escarpment into the towns of Empire and Taycheedah. Second tier development is beginning to develop along the bayshore as land on the east side of roads is being developed in order to acquire a view of the bay. Older seasonal homes are being converted or replaced with larger permanent homes and homes back from the shore are having second floors added (BLRPC, 2001).

INVENTORY METHODS

Inventory data used in this study were collected using standard methodologies developed in 1974 by The Nature Conservancy for all Natural Heritage and Conservation Data Centre programs and coordinated today by NatureServe (Stein et al., 2000). This methodology is based on determining the location, condition, and status of units of natural diversity called “elements.” Each documented instance of an element is termed an “element occurrence,” and is referenced temporally as well as spatially. Elements include rare species, natural communities, natural features, and animal concentration areas such as bat hibernacula and bird rookeries. See Appendix 2 for more information on the NHI methodology.

Existing element occurrence records for the study area and surrounding lands and waters were extracted from the NHI database and reviewed early in the study. Throughout 1999-2001, inventories were completed on sites in the study area for rare plants, rare animals (including selected invertebrates), and natural communities. Target species and communities were selected from review of existing records and review of the NHI working list, a dynamic compilation of species and natural communities tracked by the NHI program that includes global and state ranks indicating degree of rarity. In 2001 more fine-tuned inventory was conducted and all data were subsequently mapped and computerized in the NHI database. See Appendix 3 for more information on the NHI working list and ranks.

A top-down, coarse filter-fine filter approach was used for the inventories. The initial analysis focused on natural communities and aquatic features present, their relative quality and condition, the surrounding landscape patterns, and current land use. Based upon existing habitat characteristics and known habitat preferences of various rare species, sites where species-specific surveys were most appropriate were identified. ***No doubt, occurrences of rare species exist that were not located through these inventories.*** However, by concentrating inventory efforts on Escarpment-related sites, it is most likely that populations of rare species with the highest conservation value were located.

In addition to standard NHI methodology, accepted scientific protocol and procedures for the various taxa were used during the Niagara Escarpment inventory. Specific methods used for each type of inventory conducted are as follows.

RARE PLANTS AND NATURAL COMMUNITIES

Principal Surveyors: Andy Clark, Dr. Emmet Judziewicz

Field inventory was conducted between July and October of 1999, and during the summers of 2000 and 2001. Over 50 major sites were inventoried including six state parks (High Cliff, Newport, Peninsula, Potawatomi, Rock Island, and Whitefish Dunes). Inventory targets included intact landscapes, plant communities, and selected rare vascular plants. Because of constraints imposed by the physical attributes of the Escarpment (sheer cliffs, talus), the primary survey method was the “meander survey technique”, whereby as much of the site was covered as possible. This ensures that most, if not all, of the site variability and microhabitats present receive attention. Several sites were very small, or severely degraded, and field surveys were accordingly brief. An aerial survey of the Door Peninsula north of Sturgeon Bay was conducted by the NHI Ecologist in October, 2001. A list and description of natural community types associated with the Escarpment are provided in Appendix 4.

AQUATIC INVERTEBRATES

Surveyors: Dr. Kurt Schmude, Kathryn Kirk

The goal was to determine overall diversity and rare species components of aquatic habitats that are in some way influenced by proximity to the Niagara Escarpment. These sites were chosen to be surveyed because of their potentially unique and/or sensitive habitat and resident macroinvertebrate fauna, and/or because of the possible impact to the sites by actual or future land development. Emphasis was given to springs, seeps, small streams and wetlands in Door Co. Many of these sites were recommended by biologists familiar with the area. A concurrent study, funded by the U.S. Fish and Wildlife Service to locate additional populations of the Hine's emerald dragonfly, was coordinated with efforts here and is reported on separately (Kirk, 2002).

Running Water Sites. A total of 36 running water sites were sampled. At each site, the available habitats were determined, and each surveyor was responsible for a particular habitat(s). Sampling was performed using a D-frame aquatic net (approximately 1 mm mesh). The kick-sampling method was used in riffles and runs, while undercut banks were sampled by rigorously manipulating the net in the undercut substrates. Sample debris was placed on a large mesh screen over a large plastic tray, and the organisms fell through the mesh into the tray. Sample debris was then searched for cryptic, slow-moving organisms. All specimens were preserved in plastic vials containing 70% ethanol. Submerged structures (wood, rocks) were taken out of the water and inspected, and other habitats (water surface, shoreline) were visually inspected for organisms and exuviae. Habitats that were sampled included rocky riffles and runs, submerged wood and roots, undercut banks, submerged and emergent vegetation, sandy, silty, and/or clayey runs near the shoreline, surface (surface-dwelling organisms), and shorelines and bridges (exuviae).

Still Water Sites. A total of 16 still water sites were sampled. The available habitats were again determined, and each person was responsible for a particular habitat(s) or area(s) to sample. The same methods were employed. Habitats sampled included shallow vegetated areas, water column of deeper areas, submerged wood, shallow sandy/silty areas near the shoreline, surface, and shoreline searches for exuviae.

RARE BIRDS

Surveyor: Mike Grimm

Sites of expected or known high quality habitat that were especially representative of the Niagara Escarpment were selected for bird surveys. One hundred and ten point counts were made on 18 different properties. A wide range of habitats associated directly with the outcrops and bluffs of the Escarpment were selected. Habitats surveyed included vertical dolomite cliffs, upland hardwood or mixed hardwood-conifer forests at the Escarpment base, spring-fed white cedar swamps, and the thin-soiled boreal forests on dolomite along the Lake Michigan shoreline.

Three survey methods were used. At most sites a transect was established across the long axis of the survey site. Surveyors stopped at points located several hundred meters apart for 10 minutes to record all birds heard or seen. Incidental observations of birds observed between stops or flying over the site were recorded but kept separate from the more formal survey information. This method resulted in a set of 10 minute point counts for each survey site. Descriptive notes on vegetation, dominant plant species, and site condition were made at each observation point or during the return to the starting point. Where the sites were very small and/or time was limited a slow walk through the site was made, and all birds heard or seen were recorded. Lastly, one site was surveyed using a road-side count, following the methodology developed by the U.S. Fish and Wildlife Service for its continent-wide Breeding Bird Survey (3-minute observation points spaced one-half mile apart).

RARE TERRESTRIAL INVERTEBRATES

Surveyor: Kathy Kirk

Selected rare taxa from the insect Orders Lepidoptera, Heteroptera, Coleoptera, and Orthoptera were searched for in appropriate habitats. Sixty two sites were surveyed. Note that land snails were not field inventoried for this project. Survey sites were selected based on consultation with ecologists familiar with the area and in consideration of The Nature Conservancy and Door County Land Trust list of sensitive sites along the peninsula. Sites were chosen to sample a variety of Escarpment attributes such as rock structure, type and density of vegetation present, exposure, aspect, and latitude in order to represent all Escarpment habitat types available to the organisms in question. Lands in both public and private ownerships were included as accessibility and opportunity allowed. Some potential sites were visited early in the season and subsequently rejected as sampling sites.

All Escarpment sites, with the exception of one, were sampled by pitfall trapping. Traps were placed at the base of sheer faces, within the talus, or wedged into the rock as the situation allowed. Typically three traps were left at each site for 1 to 2 weeks. With few exceptions, trapping was conducted in late July. Collections were made from the rock ledges and faces by hand or aspirator at all sites. In addition, sweepnetting and handcollecting was conducted at two alvar sites.

ANALYSIS OF INVENTORY DATA

NHI staff scientists analyzed inventory data using GIS to determine which species and natural communities in the study area were specific to or most closely related to the presence of the bedrock, outcroppings, or other ecological attributes unique to the Escarpment. The species and natural communities surveyed during this project were placed in one of three classes:

Class 1. Those natural communities or rare plants or animals that are restricted to or strongly associated with near vertical or in certain cases, horizontal exposures of the Niagara Escarpment. This can include alvar communities, caves, sinkholes, crevices, talus slopes, and free face and rock ledges of the Escarpment.

Class 2. Those natural communities or rare plants or animals that are influenced by proximity with, but are not necessarily found directly on, vertical exposures of the Niagara Escarpment. Habitat and communities may include thin soiled, well drained dry-

mesic to mesic forests above the free face, various spring-dependent wetlands below talus and wetlands on near-surface dolomitic bedrock, and mesic lake plain forests below talus. This also would include Great Lakes Alkaline rockshore. This class includes features that are concentrated in the study area and are largely absent from the remainder of Wisconsin.

Class 3. Those natural communities or rare plants or animals that happen to be in the study area but have many of their occurrences in other parts of Wisconsin. This can include a subset of features that may be calciphitic or otherwise associated with the influence of a calcareous substrate.

Mesic forest, Rowley's Bay Trail. Photo by Gary Fewless.

OVERALL RESULTS

The study documented 241 occurrences of rare species and natural communities (Map 5). Of these, 106 were animal occurrences, 99 were plants, and 36 were natural communities and other natural features. Nineteen were Class 1 occurrences, 28 were Class 2, and 194 were Class 3. Highlights are summarized below, with an emphasis on those elements closely related to the Escarpment (Class 1). Each of these elements relies strongly upon the unique features of the

Escarpment in order to sustain itself, and they are generally not found in other areas of Wisconsin. In some cases, the elements are globally rare. Study results are summarized by county in the next section.

NATURAL COMMUNITIES AND NATURAL FEATURES

The rock exposures of the Niagara Escarpment have created unusual environmental conditions that support distinctive assemblages of plants and animals. The Escarpment crosses a major climatic “tension zone” (Curtis, 1959), accounting for significant differences in the vegetation around and on the Escarpment. Historically, the northern stretches were embedded in a vast regional forest composed of a diverse mixture of hardwoods and conifers. From Kewaunee County south, prairie, oak savanna, and hardwood forests comprised the regional vegetation within which the Escarpment was situated.

Currently, the landscape around the Escarpment is highly altered by agricultural, residential, recreational, and industrial developments. Only on the Door Peninsula from the Sturgeon Bay area north do substantial remnants of natural vegetation remain. The most extensive of these remnants are forests, which at some locations still cover hundreds or thousands of contiguous acres. Important canopy trees include sugar maple, beech, basswood, white pine, white cedar, red pine, paper birch, hemlock, and balsam fir. Site conditions vary from dry to wet-mesic and as a result the mosaic of forest communities can be quite complex. Lake Michigan has influenced the climate of this area, resulting in cooler summers, warmer winters, and higher precipitation than at inland locations away from the Lake.

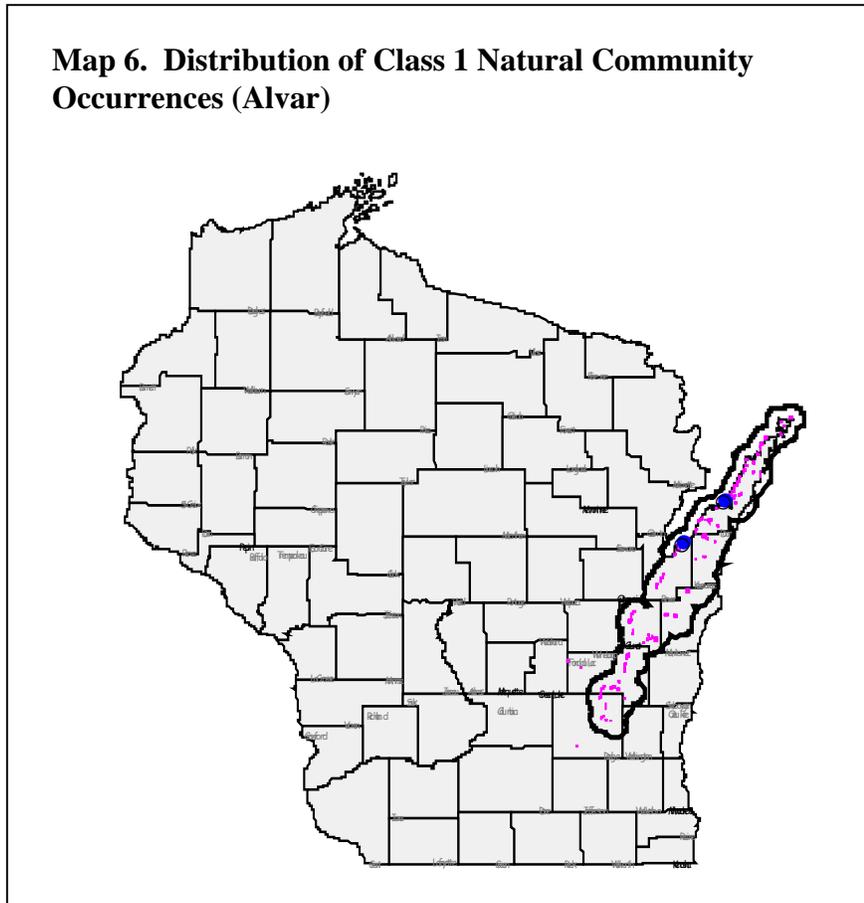

Farther south the natural vegetation is confined to the Escarpment itself, or may occur in small patches or extend in narrow strips along the Escarpment base or immediately above the rock. The “southern” forest composition consists of sugar maple, basswood, and beech on mesic sites, and mixtures dominated by oaks on drier sites. Red cedar is the only conifer regularly encountered along the southern portions of the Escarpment. No significant remnants of prairie or oak savanna communities have been documented in the immediate vicinity of the Escarpment.

Alvar. Alvar is a globally rare community found in North America only along Great Lakes shorelines (Map 6). Characteristics include thin, discontinuous soils over horizontal beds of limestone or dolomite, relatively low tree cover, and a distinctive biota that includes associates of rock pavement, prairie, oak savanna, and boreal forest communities. Among these are regional endemics, such as dwarf lake iris (*Iris lacustris*), restricted to the western Great Lakes region. Both coniferous and deciduous trees (cedar, fir, pine, oak, aspen, birch) may be scattered among an assemblage of other species that can include prairie plants like big bluestem (*Andropogon gerardii*), little bluestem (*Schizachyrium scoparium*), Indian-grass (*Sorghastrum nutans*), and wood lily (*Lilium philadelphicum*), as well as shoreline plants such as silverweed (*Potentilla anserina*) and dwarf lake iris.

Free Face and Rock Ledges. Natural communities associated with the Escarpment face include alkaline dry cliffs, alkaline moist cliffs, seeps, and talus slopes. Along the Lake Michigan shoreline of the northern Door Peninsula, exposures of dolomite provide the substrate for alkaline rockshore, cobble beach, and wave-splashed cliff communities. Future vegetation sampling is planned to produce more detailed information on these bedrock communities.

Caves, sinkholes, and crevices. Many of the Escarpment cracks have become enlarged by dissolution, and the bedrock exhibits features such as caves and sinkholes. These features allow rapid infiltration and horizontal movement of groundwater, a phenomenon unique to karst areas in Wisconsin (Valvassori, 1990). Sinkholes and associated collapse features provide direct conduits for surface water to quickly reach underlying aquifers without filtration or storage. Ancient reef formations, rich in fossil deposits, are preserved locally in the dolomitic bedrock that forms the Escarpment.

Map 6. Distribution of Class 1 Natural Community Occurrences (Alvar)

Various Spring-dependent Wetlands Below Talus or Cliff Faces. At a few locations, water flowing through the dolomitic bedrock exits at or near the Escarpment base as spring runs or seepages. Wetland communities composed of swamp hardwoods, white cedar, and/or tall shrubs develop in these areas.

PLANTS

The variety of habitats developed by the karst topography, relative inaccessibility of cliff features, and calcareous soil conditions of the Escarpment create important conditions for the unusual expression of some common plant species and the presence of many species of rare plants. For example, old eastern red cedars (*Juniperus virginiana*) occur along the Escarpment, and an undisturbed cliff near Greenleaf in Brown County might have the oldest tree in Wisconsin. Dr. Douglas Larson, director of the Cliff Ecology Research Group at the University of Guelph, studied an eastern red cedar that he estimates to be over 1,200 years old (Larson et al, 1999). In fact, this individual tree may be the oldest red cedar tree in the world.

The Escarpment supplies critical habitat for a number of endangered, threatened, and rare plant species. Some species, including small white lady's-slipper (*Cypripedium candidum*), snow trillium (*Trillium nivale*), and low calamint (*Calamintha arkansana*), are found in other parts of the state but thrive on the calcareous substrates associated with the Escarpment. Other species,

such as elk sedge (*Carex garberi*), spoon-leaf moonwort (*Botrychium spathulatum*), and small-flowered grass-of-parnassus (*Parnassia parviflora*), are found nowhere in Wisconsin but in close proximity to the Escarpment. Finally, the two species described below are dependent on bedrock exposures of the Escarpment for their existence in Wisconsin. The distribution of these Class 1 species and selected Class 2 and 3 species is shown on Map 7.

Draba arabisans (rock whitlow-grass) is a plant of Special Concern in Wisconsin. This species prefers exposed to shaded (often by white cedar) dolomite. Flowering occurs from mid-June through late July, and the optimal identification period is from early July to mid-September.

Draba lanceolata (lanceolate whitlow-cress) is a plant listed as Endangered in Wisconsin. This species prefers exposed dolomite. Flowering occurs from early May through mid-July, and the optimal identification period is from early May to late July.

***Botrychium minganense*, Newport State Park, July 15, 2000. Photo by Tim Ditzman.**

ANIMALS

One of the most striking features of the Escarpment is the presence of rare land snails, some of which date back to the last Ice Age. These snails were widespread in the Pleistocene and are restricted now (in the Midwest) to cool moist microhabitats found primarily in the Niagara Escarpment and the Driftless Area. All but one of the animal species that are tied strongly to the Escarpment are land snails. Four of the six species restricted to areas influenced by the Escarpment are also land snails. Of the 100 or so species of land snail in Wisconsin almost a third are tracked by NHI and 7 are globally rare to globally imperiled (WDNR, 2001). About 20% of Wisconsin's land snail fauna are imperiled to critically imperiled in the state. Three species are currently protected as Endangered or Threatened. Most of these rare snails are species of cliffs and are either restricted to the Driftless Area of southwestern Wisconsin or the Niagara Escarpment of northeastern Wisconsin or both. A few species use woodlands or wetlands rather than cliffs. All of these rare snails are very small, with shell diameters of only a few millimeters.

The 16 species that are restricted to areas influenced by the Escarpment (Class 1 species) are described below, along with one Class 2 species (Hine's Emerald dragonfly) that is closely associated with the Escarpment. Other noteworthy animal-related features are also described. See Map 8 for distribution of these elements in Wisconsin.

Catinella gelida (a land snail), a State Special Concern snail. This species appears to be restricted to moist, soil covered ledges in the southern half of the study area, except for one record in Shawano County.

Glyphyalinia rhoadsi (sculpted glyph), a State Special Concern snail. This species is typically found in mesic woodlands near an alvar community. Five of the state's 6 known populations of this species occur in the northern half of the study area.

Glyphyalinia wheatleyi (bright glyph), a State Special Concern snail. This species is typically found in mesic woodlands and its only record in the state occurs in the middle of the Door Peninsula.

Hendersonia occulta (cherrystone drop), a State Threatened snail. This species is found on cliffs, algific slopes, and lakeshore woods. There are fifty-two populations documented in the state, thirty-five of which occur in the northern two-thirds of the study area.

Paravitrea multidentata (dentate supercoil), a State Special Concern snail. This species occurs primarily in deciduous forests in proximity to Lake Michigan and on cliffs along the Niagara Escarpment in eastern Wisconsin.

Pupoides albilabris (white-lip dagger), a State Special Concern snail. This species typically occurs in calcareous grasslands. The only known state occurrence of this species is in the middle of the study area in Brown County.

Striatura ferrea (black striate), a State Special Concern snail. This species is typically found in mesic woods in the northern half of the study area.

Striatura milium (fine-ribbed striate), a State Special Concern snail. This species typically occurs in mesic woods, cliffs, and algific slopes across its range. The only known state occurrence is in the northern half of the Door Peninsula.

Succinea bakeri (a land snail), a State Special Concern snail. This glacial endemic species occurs only along the Niagara Escarpment in eastern Wisconsin. It is restricted to cool carbonate talus slopes, cliffs, and algific slopes, often occurring with other glacial relict taxa.

Vallonia perspectiva (thin-lip vallonina), a State Special Concern snail. This species occurs primarily along calcareous cliffs in the southern half of the study area.

Vertigo elatior (tapered vertigo), a State Special Concern snail. This species occurs primarily in or near fens. They have been found in the northern half of the study area.

Vertigo hubrichti (midwest pleistocene vertigo), a State Endangered snail. This species occurs primarily on algific slopes and cliffs.

Vertigo iowaensis (Iowa pleistocene vertigo), a State Special Concern snail. This species occurs primarily on algific slopes and cliffs.

Vertigo nylanderi (deep-throated vertigo), a State Special Concern snail. This species is a rare calciphile found in swamp and alvar communities in the northern half of the study area.

Vertigo paradoxa (mystery vertigo), a State Special Concern snail. This species occurs primarily on cliffs.

Zoogenetes harpa (boreal top), a State Special Concern snail. This species occurs primarily on cliffs, and rocky and/or wet woods.

Somatochlora hineana (Hine's emerald dragonfly), a state endangered dragonfly, recently federally listed. The larval stage of the Hine's emerald is apparently restricted to spring-fed marshes, rivulets through emergent herbaceous vegetation, or small open water pools in the boreal rich fen community, where the water has groundwater sources, but may seasonally dry up. This may be due to the fact that most sites are perched just above dolomitic bedrock. Larvae may be dependent in some locations on the presence of crayfish burrows to survive summer drought or to over winter. Adults forage widely over surrounding areas and seem to prefer forest - open area edges. They rest in trees and shrubs and roost overnight in trees. The flight period extends from mid June through mid to late August. Door County has the largest population of this federally endangered species known.

Bat Hibernacula. One of the largest bat hibernacula in the Upper Midwest occurs at the Neda Mine State Natural Area (WDNR, 1989), near the southern end of the Niagara Escarpment. The caves, sinkhole features, and excavations associated with the former mine, provide summer roosting and winter hibernating sites for significant numbers of bats. Other areas of the Escarpment, e.g., at Door County's Peninsula State Park, are also known to harbor bats but the regional and local significance of these sites is unclear.

Migratory Bird Routes. While not directly dependent on the Escarpment, numerous migratory birds use the Escarpment in some way during their spring and fall migrations because it is congruent to shoreline. Waterfowl, particularly Canada Geese occupying nearby Horicon Marsh, may use the Escarpment as a "land mark" on return trips to the marsh.

Fish Spawning Areas. Submerged dolomite reefs and ledges off the Door Peninsula receive significant use by spawning whitefish (*Coregonus clupeaformis*) and other species.

INVENTORY RESULTS BY COUNTY

Inventory results are presented by county, arranged from north to south, within the study area. Each account includes a brief description of the study area within the county and a map of the county showing Escarpment outcroppings and occurrences of rare species and natural communities. The known element occurrences in each county are also presented in three tables based on the three classes: those dependent on the Escarpment (Class 1), those influenced by their proximity to the Escarpment (Class 2), and those that happen to be in the study area but are not necessarily dependent on the Escarpment (Class 3). Outagamie, Sheboygan, Washington, and Winnebago counties contain only insignificant portions of the study area and therefore are not described below.

DOOR COUNTY

Door County is almost entirely (97%) within the study area. The Niagara Escarpment is most prominent in Door County, with many outcroppings occurring along the eastern margin of Green Bay, along Lake Michigan in the northeastern part of the county, and on some of the larger islands making up the Grand Traverse archipelago.

The soils of Door County related to the Escarpment include rock outcrop and rock outcrop-Namur complex. This includes steep to nearly vertical exposures of dolomite bedrock, and stones on escarpments and talus slopes in areas where dolomite is exposed. Soils along these exposures are generally less than 12 inches thick and runoff is rapid. Namur soils have moderate runoff (U.S.D.A Soil Conservation Service, 1974).

Land use is highly variable. Residential development pressure is increasing, with shoreline areas or other sites with a lake view (e.g., the Escarpment!) especially vulnerable. Agricultural use is dominant in the interior of the county, and occurs at scattered locations elsewhere. Significant forests occur in Door county, most extensively near the Lake Michigan – Green Bay shorelines and often associated with areas that have thin soils overlying the dolomitic bedrock. There are five state parks in Door County and recreational use is extremely heavy. Several privately owned nature preserves are also present.

Door County is ecologically diverse, and many exceptional natural communities and rare species populations have been documented by biologists from public agencies, universities, and private conservation organizations. This county has the highest number of Class 1 rare species of any county in the study area. Many of the species are land snails of which at least two species are globally imperiled. One is the federally endangered Hine's emerald dragonfly which has the best populations here of anywhere in its range. Botanists have documented two species of whitlow-grass on cliffs in Door County that in Wisconsin are confined to the Escarpment. Not only is Door County rich in Class 1 species, but there are also many Class 2 and Class 3 rare plants and animals. Forty-one of the Class 2 and Class 3 species are listed as threatened or endangered by the state of Wisconsin, and four of these are on the Federal list of threatened or endangered species. Several plants, such as striped maple and broad-leaf sedge, are found nowhere else in Wisconsin. Door County has one of only two documented occurrences in the state of the globally unusual alvar community. The many high quality communities documented in Door County include Class 2 Great Lakes alkaline shorelands and talus forest. Some of the Class 3 communities are boreal rich fen, Great Lakes beach, interdunal wetlands, and shore fen. The rich array of rare species, natural communities, and special features is listed in the tables below.

KEWAUNEE COUNTY

As with Calumet and Door counties, most (96%) of Kewaunee County is in the study area. Outcrops of the Escarpment are concentrated in the northern two-thirds of the western two-thirds of the county. There are scattered outcrops in the southern one-fifth of Kewaunee County.

As is typical of the other counties in the study area, land use in Kewaunee County is a mixture of agriculture, forest, and development. Within the study area, there is heavy residential and commercial development in the northwest corner of the county along Green Bay.

Compared to other counties that are mostly within the study area, Kewaunee County has relatively few Class 1 species. All of the Class 1 species are land snails, one of which may be globally imperiled. There are two Class 2 animal species and one Class 2 plant species in the study area. One of the animals, Hine's emerald dragonfly, is listed as endangered both by Wisconsin and the Federal government. Six of the Class 3 animal and plant species documented in Kewaunee County are listed as endangered or threatened in Wisconsin. BER staff documented relatively few high quality natural communities in the county, but they included a Class 2 moist cliff and Class 3 emergent aquatic and southern mesic forest communities, among others. The rare species and natural communities are listed in the tables below.

BROWN COUNTY

Approximately 69% of Brown County lies within the study area. Exposures of the Niagara Escarpment run from the northeast to the southwest part of the county.

Brown County is one the most populated counties in the study area, particularly in the Green Bay area. Consequently, land use is variable, with heavy development pressure in the vicinity of the City of Green Bay. The remainder of the study area in Brown County is a mixture of small forest patches, agriculture, low density housing, and quarry operations of differing sizes.

There are a number of significant endangered resources in Brown County. One of only two known occurrences of the alvar natural community has been described in Brown County. The microclimate resulting from the geology of the Niagara Escarpment harbors a variety of rare and unusual land snails, including several species that are globally imperiled. Many other high quality natural communities and rare species occur near and are influenced by the Escarpment. These include the Class 2 moist cliff and several Class 3 communities such as forested ridge and swale, northern dry-mesic forest, and stream-slow, hard, warm. There are 16 Class 2 and 3 plants and animals that are listed as endangered or threatened by Wisconsin, including one species, the dwarf lake iris, that is listed as threatened by the federal government. The species and natural communities are listed in the three tables below.

MANITOWOC COUNTY

About 59% of Manitowoc County is in the Niagara Escarpment study area. The Escarpment outcroppings are restricted to the north-central and west-central parts of the county. Land use in the county is a mix of agriculture, forest, and development. The major cities are Manitowoc and Two Rivers.

Only two Class 1 species have been documented on the outcrops of the Escarpment in Manitowoc County. Both species are land snails one of which is listed as endangered and the other as threatened in Wisconsin. Each species has been found in only three to four other counties in the study area. Of the 17 Class 2 or Class 3 rare species in the study area, six have been listed as endangered or threatened by the state of Wisconsin. The county has several high quality examples of natural communities, including Class 2 moist cliff and Class 3 communities like lake-soft bog and northern mesic forest. The various species, natural communities, and special features are listed in the three tables below.

CALUMET COUNTY

The vast majority (about 95%) of Calumet County is in the study area. The Niagara Escarpment outcrops are concentrated in the southwestern two-thirds of the county, especially along the east shore of Lake Winnebago, with scattered outcrops in the northeast.

Land use in the study area includes agriculture and forest with some rural residential development. A large tract of forest exists south from Sherwood to High Cliff State Park. There is considerable development in the study area along Lake Winnebago in western Calumet County.

Survey work was successful in locating new populations of several species of rare Class 1 land snails, including one that is globally imperiled. Three high quality examples of Class 2 natural communities (moist and dry cliffs, talus forest) have been documented in the county as well as a bat hibernaculum. The natural communities are dependent on the properties of the geology that results in the formation of cliffs and talus slopes. Class 3 communities include emergent marsh, floodplain forest, and open bogs. There is seven Class 2 or 3 species that are listed as endangered or threatened by Wisconsin. The natural communities and species are listed in the three tables below.

FOND DU LAC COUNTY

About half (52%) of Fond du Lac County is in the study area. The Escarpment runs north to south in about the central third of the county, and is a prominent feature near the southeastern shore of Lake Winnebago and southwest of the village of Oakfield. There are scattered outcrops near the western border of Fond du Lac County.

Land use is predominantly agricultural and residential, with very limited timber management occurring in a few areas. Within the study area, development is most extensive in and around the City of Fond du Lac and along the busy the USH 41 corridor. Development is also concentrated along the Lake Winnebago shoreline.

Although Fond du Lac County was not surveyed as thoroughly as most of the other counties, five Class 1 animal species and one Class 1 plant have been documented. The animal populations are all land snails that depend on the microclimate created by the Escarpment. At least two of the snail species are considered globally imperiled. In Wisconsin, rock whitlow-grass has been nowhere but on the cliffs of the Escarpment. Nineteen other high quality examples of natural communities and rare species, including five species listed as threatened in Wisconsin, have been found in Fond du Lac County. The natural communities include a Class 2 moist cliff, a Class 2 dry cliff, and Class 3 floodplain forest, southern sedge meadow, and mesic prairie, among others. The rare species and natural communities are outlined in the tables below.

DODGE COUNTY

About 29% of Dodge County is in the study area. The most significant outcrops of the Escarpment are in the northeast part of the county, with scattered outcrops elsewhere outside of the study area.

The land use in Dodge County includes agriculture and forest. Development in the study area is centered on the cities and villages, with scattered rural residential development elsewhere. The Escarpment is quarried at several locations, with a large operation at the intersection of STH 67 and 33.

A number of high quality natural communities, special features, and rare species have been documented in the study area in Dodge County. High quality natural communities include a Class 2 moist cliff, Class 2 dry cliff, and Class 3 emergent aquatics and southern mesic forest. A Class 2 special feature, a bat hibernaculum, has been documented in the study area. All of the Class 1 rare species are land snails, including three species that are globally imperiled. Three of the Class 3 rare taxa are listed as endangered or threatened by the State of Wisconsin. The natural communities, special features, and rare species are listed in the tables below.

THREATS AND MANAGEMENT CONSIDERATIONS

The purpose of this section is to summarize the threats that were identified during the inventory and by reviewing other reports. Management considerations related to conserving the Escarpment's biodiversity are also provided.

CURRENT THREATS

Land use issues, conflicts, problems. An analysis done by the Bay-Lake Regional Planning Commission in 2001 compared land use controls and discussed how each affects protection of the resources in the Niagara Escarpment study area. Several problems and conflicts between land use plans and existing regulations were noted. Land use comprehensive plans developed by various units of government were often not consistent with local zoning. For example, county plans were not consistent with town plans, and areas were classified differently under their respective plans and did not cross civic borders. Most of the existing plans do not recognize the Escarpment as a unique natural feature.

Development. One of the most pressing threats to the Niagara Escarpment is residential development. As the population of Wisconsin increases, cities and villages in the study area continue to grow. The natural beauty of the Door Peninsula draws many tourists year-round, and there has been a rise in second-home development. There is increasing pressure to construct piers and areas for boat launches on the adjoining Lake Michigan shoreline. In areas where there has been limited development in the past, the construction of homes and associated infrastructure fragments the sensitive habitats and may destroy habitat for rare plants and animals.

Road construction. As the year-round population and popularity of the study area as a recreational destination increase, highway construction and expansion will intensify. Higher capacity roads will likely increase development along the Escarpment by providing easier and faster access between the Door Peninsula and Green Bay. Hydrologic disruption and outright destruction of some of the Escarpment features may occur due to road construction or upgrading.

Mining, quarrying. Due to the relatively thin layer of soil and the relative ease in accessing bedrock, quarries of varying sizes have been and continue to be developed at several locations along the Niagara Escarpment. Quarrying is tied to development as various resources are extracted for construction materials. The Escarpment is used as a resource for the gravel and crushed stone used in construction of roads and residences, and for flagstone for home business development. Quarrying can have several impacts including the obvious direct habitat destruction and fragmentation. A less obvious effect of mining can be the alteration the hydrology and microclimate of the Escarpment.

Tower areas. Because of the topography and location of the Niagara Escarpment, utility companies have become interested in using it as a wind generator location. The construction of cellular, television, and radio towers has increased dramatically in recent years and this trend will likely continue or increase. Towers may have detrimental impacts on bird populations, and result in a loss in scenic beauty in the area.

Recreation. As the Escarpment has increased in popularity, the demand for recreational opportunities has also increased. Increased visitation to popular public lands in the study area can result in overuse of designated trails and the development of unauthorized casual use trails. Additionally, trails can serve as conduits for the introduction of invasive species. Designing trails that lead to and from the Escarpment rather than along it would diminish some of the associated overuse problems. Re-routing certain existing trails could also limit excessive disturbance. As mentioned above, recreational demands will likely result in the construction of new piers, boat landings, parking areas, and access roads.

Invasive/exotic species. As natural habitats become more fragmented and disrupted and as visitor use increases, invasive species can be accidentally or deliberately introduced into high quality habitat. Uplands and wetlands may be vulnerable to aggressive invasive species like exotic buckthorns (*Rhamnus* spp.) and honeysuckles (*Lonicera* spp.), garlic mustard (*Allaria petiolaris*), purple loosestrife (*Lythrum salicaria*), reed canary grass (*Phalaris arundinacea*), and

The largest plants of *Taxus canadensis* were on dolomite rock, out of the reach of deer. Photo taken in Newport State Park by Gary Fewless.

non-native strains of common reed (*Phragmites australis*). “Escaped” garden plants have also created local infestations that need to be carefully monitored, and removed as possible. Surface waters are not exempt either as aquatic plants like Eurasian water milfoil or animals like sea lampreys, spiny water fleas, zebra mussels, and carp can invade them (Corbisier et al., 2000). Invasive species can displace or eliminate native species, particularly rare species that have specific habitat requirements. Invasive species can substantially alter the structure and functioning of high quality natural communities. Abundant native species can also have negative ecological impacts, with excessive browse pressure from white-tailed deer in some Door County parks being the most notable example.

Hydrologic disruption. Springs, sinkholes, caves, and other karst features provide unique habitats for a vast array of rare species and natural communities, many of which are susceptible to hydrologic disruptions. For example, new construction can directly or indirectly affect groundwater infiltration rates and consequently change the amount of water that discharges from a spring. The other threats listed above can, directly or indirectly, alter the hydrologic cycle and thereby change the conditions necessary for the continued health of rare species populations and some natural communities.

Communities, especially wetlands, in the study area that are not on karst may also be subject to hydrologic disruptions. Wetlands ecosystems are important for many reasons, functionally (groundwater recharge areas, buffers, and water retention areas) and biologically (habitat for rare species, spawning areas for fish, prime nesting sites for birds). Hydrologic disruptions such as

draining or isolation alter the functioning of wetlands and reduce or eliminate important habitat for many species.

Groundwater contamination. Groundwater is an important source of potable water, and groundwater contamination has been a significant issue along the Escarpment for some years (Valvassori 1990). In areas of karst in the study area, pathways develop for water movement through the rock leading directly to the groundwater with little or no filtration. Surface activities such as agriculture (both crops and grazing), road salting, and non-point source pollution can contaminate water moving directly into the groundwater. The thin soils in the area can create other difficulties including the adverse effects of leaking underground storage tanks or deteriorating septic tanks.

Administrative inconsistency. The Escarpment is a natural feature of regional significance that crosses jurisdictional boundaries of local, county, state, and federal governments. The maze of overlapping, and sometimes conflicting, land use regulations and guidelines contributes to the difficulty in making progress toward effective conservation partnerships and actions.

MANAGEMENT CONSIDERATIONS

This section describes actions that will contribute to conservation of the Niagara Escarpment's biodiversity. They are grouped into 3 broad categories: monitoring and management, protection and planning, and communication and landowner education, and inventory needs.

MONITORING AND MANAGEMENT

Once high quality natural communities, rare species, and special features have been identified, it becomes important to attempt to perpetuate those features. The following are basic approaches that land managers can use to maintain important occurrences.

Monitoring. Monitoring changes is an important tool in determining the long-term health of and changes to natural communities and sensitive species populations. A long-term monitoring program is needed for populations of selected listed species, high quality natural communities, and state natural areas. Benchmark data can be collected at these locations to monitor changes over time. The comparison of results of monitoring over time with benchmarks can suggest appropriate management strategies.

Removal of invasive species. As mentioned above, invasive species can disrupt natural communities and displace rare species. Sites throughout the study area are threatened by invasive species. Routine identification and removal of invasive species, particularly those that are the most aggressive, is an urgent need. Prevention and rapid identification are key elements in minimizing the spread of invasive species.

Trail construction/expansion. Trails directly impact sensitive areas and can provide conditions for the establishment of invasive plants and corridors for their further spread. Invasive species may inadvertently be introduced on trails not only by visitors but also by trail maintenance

workers. Land managers should be aware of the potential ecological impacts of trail widening and construction.

PROTECTION AND PLANNING

To help maintain important element occurrences in the study area for the long-term, it may be necessary to look beyond individual properties and coordinate efforts among a diverse group of stakeholders. The following can provide some guidance in that direction.

Protection Efforts. A number of the inventoried sites are large contiguous tracts, some of which are adjacent to designated natural areas. Important properties should be linked together by some type of protection mechanism. Some mechanisms that should be considered are outright purchase, conservation easements, or dedication as State Natural Areas. A master list of priority sites in the study area should be developed and subsequent protection efforts should focus on these areas.

Planning. The BLRPC (2001) reports that some towns have not adopted zoning ordinances, and there isn't consistency in zoning from county to county much less town to town within the same county. As identified in the Bay-Lake Regional Planning Commission (2001) report, many of the existing land use plans and zoning ordinances along the Niagara Escarpment do not consider the unique ecological functions and attributes of the study area and are not therefore not compatible or consistent with the existing ecological features. For instance, in farmland preservation plans, the Escarpment is not recognized as an ecologically important area with the exception of those areas inside a park (classified as an "excluded area"). An attempt to integrate planning between local, state, and federal agencies should be a priority. Detailed planning recommendations can be found in the Bay-Lake Regional Planning Commission report.

COMMUNICATION AND LANDOWNER EDUCATION

While it is very important to obtain high quality information about elements of biodiversity in the study area, it is equally important to communicate the results to land managers and landowners.

Communication. It is hoped that the inventory results will be shared and discussed by landowners, land managers, agency personnel, local conservation groups, and other decision-makers. Visitors to public lands in the study area should be made aware of the geology and ecology of the many special features. Staff managing areas of special ecological significance and sensitivity on state, county, or local public lands will have special use for this information. A dialogue between managers and Natural Heritage Inventory Staff should continue to be an important outcome of this study. Researchers in Michigan and eastern Canada involved in Escarpment issues will continue to be important information sources.

Landowner stewardship. An attempt should be made to work with private landowners to inform them of the ecological significance of their properties and how to effectively manage them. Alternatives, such as conservation easements or tax law incentives, should be presented to landowners to enroll their land in some sort protection status.

INVENTORY AND RESEARCH NEEDS

While the inventory of the study area examined many sites and many elements, there is need to conduct additional work.

Additional aquatic surveys. Additional aquatic sites and habitats should be sampled in the study area to further understanding of the ecology and distribution of rare species and natural communities.

Bat roosts and hibernacula. Conservation significance of many Escarpment sites is inadequately documented and understood.

Vegetation sampling. More detailed characterization of Escarpment-associated bedrock communities is needed to better understand the structure, composition, and function of the vegetation. In addition to vascular plants, lichens and mosses will be important groups to study.

APPENDIX 1. GLOSSARY OF TERMS USED IN THIS REPORT

Algific - cold-producing, referencing certain geological structures in calcareous rock that produce very cool, humid microclimates, unusual for the latitudes they are occurring in. Rare species, some thought to be Ice Age relics, have been documented in association with these habitats.

Alvar - a rare community that consists of areas of thin discontinuous soil overlying horizontal beds of limestone or dolomite found along Great Lakes shorelines. Relatively low tree cover and a distinctive biota that includes elements of rock pavement, prairie, savanna and boreal forest communities characterize them. Among these are regional endemics, some very rare.

aquatic macrophyte - vascular plants with special adaptations to aquatic habitats (lakes, streams, springs).

BER - Bureau of Endangered Resources of WDNR

complex - used here to reference an integrated mosaic of natural communities and/or aquatic features.

cueta - a ridge composed of gently tipped rock strata with a long, gradual slope on one side and a relative steep scarp or cliff on the other.

diversity - used in this report as a shortened form for biological diversity, or biodiversity. A general definition (Addis et al., 1995) is "the spectrum of life forms and the ecological processes that support and sustain them. Biological diversity is a complex of four interacting levels: genetic, species, community, and ecosystem."

dolomite - a sedimentary, often bedded rock similar to limestone but differing due to the addition of magnesium ions.

ecological landscape - a classification that describes geographic areas according to specific geology, climate, topography, plant communities, soil types, natural processes, and other ecological factors.

ecoregion - geographic units that are differentiated by climate, subsurface geology, physiography, hydrology, soils, and vegetation. These units have been defined and organized in different ways by various agencies and institutions but in this document we use the National Hierarchical Framework of Ecological Units (NHFEU). As described by Avers et al (1994), the NHFEU can provide a basis for assessing resource conditions at multiple scales.

element - the basic building blocks of the Natural Heritage Inventory. They include natural communities, rare plants, rare animals, and other selected features such as colonial bird rookeries, bat hibernacula, and mussel beds. In short, an element is any biological or ecological entity upon which we wish to gather information for conservation purposes.

element occurrence - an individual example of an element (a natural community, a rare plant population, a rare animal population, or other feature tracked by the Natural Heritage Inventory program) at a specific geographic location.

exuviae - the cast (shed) exoskeleton of an invertebrate. –OR—The sloughed-off skin or covering of an animal, especially an arthropod.

fen - wetlands that receive nutrients via direct contact with mineral enriched groundwater. A "poor" fen has very low concentrations of plant nutrients and floristically resembles a bog. A "rich" fen has relatively high concentrations of nutrients, but is still characterized by the accumulation of peat (though this is likely to be primarily from the remains of plants other than sphagnum mosses, such as sedges and brown mosses).

fragmentation - the breaking up of large and continuous ecosystems, communities, and habitats into smaller discontinuous areas that are surrounded by altered or disturbed lands or aquatic features.

habitat - references those environmental attributes necessary to provide a niche that supports the needs of a species or group of species.

karst - terrain with distinctive characteristics of relief and drainage resulting from the dissolution of soluble rocks such as limestone and dolomite.

macroinvertebrate - Used in the report to refer to aquatic insects and mollusks.

matrix - used in this document to refer to the dominant land cover within which other features of the landscape are embedded.

monitoring - the repeated censusing of a species, suite of species, natural community or other feature of interest.

moraine - landforms composed of unsorted materials deposited by glaciers. They can cover broad geographic areas of millions of acres. Topography can vary from nearly level "till" plains to rough end moraine landscapes composed of steep dry ridges interspersed with deep kettle holes. These glacial "kettles" are frequent locations for lakes and wetlands.

National Hierarchical Framework of Ecological Units (NHFEU) - a land unit classification system developed by the U.S. Forest Service and many collaborators. As described by Avers et al (1994): "The NHFEU can provide a basis for assessing resource conditions at multiple scales. Broadly defined ecological units can be used for general planning assessments of resource capability. Intermediate scale units can be used to identify areas with similar disturbance regimes. Narrowly defined land units can be used to assess specific site conditions including: distributions of terrestrial and aquatic biota; forest growth, succession, and health; and various physical conditions."

natural community - an assemblage of plants and animals, in a particular place at a particular time, interacting with one another, the abiotic environment around them, and subject to primarily natural disturbance regimes. Those assemblages that are repeated across a landscape in an observable pattern constitute a community type. No two assemblages, however, are exactly alike.

Natural Heritage Inventory - a methodology developed by the Science Division of The Nature Conservancy for collection, management, and use of biological, ecological, and related information. In Wisconsin, the Natural Heritage Inventory was established by an act of the state legislature in 1985, after which the program was installed within the WDNR's Bureau of Endangered Resources.

northern hardwoods - generally applied to those forests of northern Wisconsin composed primarily of hardwoods such as sugar maple, basswood, ash, and birch. It is also sometimes used to refer to forests with a significant component of red maple or red oak, or sometimes even aspen, but

which lack strong representation by coniferous species. The term is also in wide usage in Michigan, northern Minnesota, and other locations that have vegetation similar to that of northern Wisconsin.

outwash - composed of materials sorted and deposited by glacial meltwaters. The resulting topography can be a level plain (“uncollapsed”) or very hilly (“collapsed” or “pitted”). Pitted outwash may contain numerous lakes, which originated when blocks of ice stranded by a receding glacier were buried within outwash deposits. As the ice melted, depressions were created that filled with water. This is the most extensive landform found on the NH-AL SF.

peat - organic deposits consisting of the partially decomposed remains of plants, which accumulate over time more rapidly than decomposition processes can break them down. Peat may be derived from the remains of mosses, sedges, or woody plants.

Pleistocene - in the geologists parlance, “the first epoch of the Quaternary Period.” In more common usage, the Ice Age. The topography, soils, and drainage patterns of the Escarpment landscape were strongly influenced by glaciation, which last occurred in this area approximately 12,000 years ago.

Rare - used in this report to refer to native species and natural communities known or suspected to be rare and/or declining in the state (included on NHI’s “Working List”). Included are species legally designated as “Endangered” or “Threatened” by either the State of Wisconsin or the federal government, as well as species in the Department’s advisory “Special Concern” category and on the U.S. Fish & Wildlife Service’s “Candidate” and “Species of Concern” lists.

restoration - used in this report to refer to the re-establishment of a natural community, habitat, species population, or other ecological attribute, that has been eliminated or greatly reduced on a given location. Many factors, sociological as well as ecological, must be weighed when making a decision to engage in a restoration project.

State Natural Area - sites formally designated by the WDNR that contain outstanding examples of native biotic communities and are often the last refuges in the state for rare and endangered species of plants and animals. Areas are devoted to scientific research, the teaching of conservation biology, and especially to the preservation of their natural values and genetic diversity for future generations. The Department of Natural Resources currently administers 335 State Natural Areas encompassing more than 123,000 acres of land and water.

survey site - the geographic location at which a biological survey or evaluation has been conducted. Survey sites may be large or small, depending on the nature of the species or community surveyed and other factors. The boundaries of a survey site may be finite and discrete (a property boundary, the margins of a single stand of a natural community, or even the limits of a rare plant population) or rather arbitrary. When sites become very large (exceeding several thousand acres) and encompass complex landscapes they may be referenced as “macrosites.”

Tension zone – the northern and southern portions of the basin are roughly divided by the tension zone, a narrow region extending from northwest to southeast across Wisconsin, approximating an s-shape (Fig. 2). The tension zone separates the mixed conifer-hardwood forests of the north from the prairie/savanna/hardwood forests of the south. Many native plant and animal species occupy ranges roughly delineated by the tension zone.

TNC - The Nature Conservancy, a private conservation organization responsible for developing the standardized methodology used by Natural Heritage programs.

WDNR - Wisconsin Department of Natural Resources

APPENDIX 2. OVERVIEW OF NHI METHODOLOGY

Natural Heritage Inventory Overview and General Methodology

The Wisconsin Natural Heritage Inventory program is part of an international network of NHI programs. The defining characteristic of this network, and the feature that unites the programs, is the use of a standard methodology for collecting, processing, and managing data on the occurrences of natural biological diversity. This network of data centers was established by The Nature Conservancy and is currently coordinated by NatureServe, an international non-profit organization.

Natural Heritage Inventory programs focus on rare species, natural communities, and other rare elements of nature. When NHI programs are established, one of the first tasks facing the staff is to consolidate existing information on the status and location of rare elements. Before proceeding, the NHI program must determine what elements warrant "tracking" and which are more common. Similar to most states, Wisconsin biologists had a general idea of which species in the better-studied taxonomic groups (e.g., mammals, birds, and vascular plants) were rare or declining. For less-studied groups such as macroinvertebrates, the process of assembling the list of species to track and gathering the data were quite dynamic. Initially, NHI staff cast a wide net, collecting data on many species from existing sources (e.g., scientific literature, field guides, books, maps, and museum collections) as well as from direct contact with experts throughout the state. As more data were gathered, it was clear that some species were more common than originally thought and the NHI program stopped collecting data on them. Thus, the list of which elements are tracked, the NHI Working List, changes over time as species' populations change (both up and down) and as our knowledge about their status and distribution increases. This evolution continues today, with the NHI Working List typically going through several revisions a year. The most current Wisconsin Natural Heritage Working List for the State of Wisconsin as of this writing (dated December, 2001) is available through the NHI office.

In general, there are two approaches to surveying biodiversity: (1) those focused on locating occurrences of particular elements, and (2) those focused on assessing the components of a particular area. The latter approach employs a "top down" analysis that begins with an assessment of the natural communities and aquatic features present, their relative quality and condition, the surrounding landscape pattern, and current land use and results in the identification of future species-oriented surveys. This approach, commonly referred to as "coarse filter-fine filter," concentrates inventory efforts on those sites most likely to contain target species. It also allows sites to be placed in a larger, landscape context for more broad applications of ecosystem management principles.

NHI inventories typically use the top-down, coarse filter-fine filter approach. The initial analysis assesses the entire region and determines the important ecological attributes and the biological processes supporting them. Criteria to evaluate sites are established and then vegetative communities are identified and characterized. Based upon existing habitat characteristics and known habitat preferences of various rare species, sites where species-specific surveys were most appropriate are identified. ***No doubt, occurrences of rare species exist that are not located through these inventories.*** However, by concentrating inventory efforts on the highest quality or

otherwise suitable sites, it is most likely that the populations with the highest conservation value are located.

The NHI methodology for organizing and storing data is actually a system of three inter-related data storage techniques: structured manual information files, topographic map files, and a computer database that integrates the various information. The computer component, known as the Biological & Conservation Data System (BCD), was developed by The Nature Conservancy for use by the Heritage Network. It is a sophisticated relational database management application built upon the Advanced Revelation application environment. Owing to the diversity and complexity of the information managed--from species taxonomy and ecosystem classification to real estate transactions--the system contains 36 database files and more than 2,000 information fields. The data in the Biological & Conservation Data System populate the NHI Geographic Information System.

INVENTORY METHODS

The following is a description of standard NHI methods for conducting NHI inventories. Any step may be modified, dropped, or repeated as appropriate to the project.

File Compilation: Involves obtaining existing records of natural communities, rare plants and animals, and aquatic features for the study area and surrounding lands and waters from the Biological & Conservation Data system, housed within DNR's Natural Heritage Inventory. Other databases with potentially useful information may also be queried, such as: forest stand/compartments reconnaissance, which is available for many public agency owned lands; the DNR Surface Water Resources series for summaries of the physical, chemical, and biological characteristics of lakes and streams (statewide, by county); the Milwaukee Public Museum's statewide Herp Atlas; museum/herbarium collections for various target taxa; soil surveys; and the fish distribution database (by watershed, WDNR-Research).

Additional data sources are sought out as warranted by the location and character of the site, and the purpose of the project. Manual files maintained within the Bureau of Endangered Resources contain information on a variety of subjects relevant to the inventory of natural features and are frequently useful.

Literature Review: Field biologists involved with a given project consult basic references on the natural history and ecology of the region within which the study area is situated. This can both broaden and sharpen the focus of the investigator.

Target Elements: Lists of target elements including natural communities, rare plants and animals, and aquatic features are developed for the study area. Field inventory is then scheduled for the times when these elements are most identifiable or active.

Map Compilation: USGS 7.5 minute topographic quadrangles serve as the base maps for field survey and often yield useful clues regarding access, extent of area to be surveyed, developments, and the presence and location of special features.

WDNR wetland maps consist of aerial photographs upon which all wetlands down to a scale of 2 or 5 acres have been delineated. Each wetland polygon is classified based on characteristics of vegetation, soils, and water depth.

Ecoregion maps are useful for comprehensive projects covering large geographic areas such as counties, national and state forests, and major watersheds. These maps integrate basic ecological information on climate, landforms, geology, soils, and vegetation. As these maps evolve, they should become increasingly useful, even for relatively small, localized projects.

Geographic Information Systems (GIS) are increasing our ability to integrate spatial information on lands and waters of the state and are becoming a basic resource tool for the efficient and comprehensive planning of surveys and the analysis of their results.

Aerial photographs: These provide information on a study area not available from maps, paper files, or computer printouts. Examination of both current and historical photos, taken over a period of decades, can be especially useful in revealing changes in the environment over time.

Original Land Survey Records: The surveyors who laid out the rectilinear Town-Range-Section grid across the state in the mid-nineteenth century recorded trees by species and size at all section corners and along section lines. These notes also record general impressions of vegetation, soil fertility, and topography, and note aquatic features, wetlands, and recent disturbances such as windthrow and fire. As these surveys typically occurred prior to extensive settlement of the state by Europeans, they constitute a valuable record of conditions prior to extensive modification of the landscape by European technologies and settlement patterns.

Interviews: Interviews with scientists, naturalists, land managers or others knowledgeable about the area to be surveyed often yield information not available in other formats.

Analysis of Compiled Information: The compiled information is analyzed to identify inventory priorities, determine needed expertise, and develop budgets.

Meetings: Planning and coordination meetings are held with all participants to provide an overview of the project, share information, identify special equipment needs, coordinate schedules, and assign landowner contact responsibilities. Team development may be a part of this step.

Aerial Reconnaissance: Fly-overs are desirable for large sites, and for small sites where contextual issues are especially important. When possible, this should be done both before and after ground level work. Flights are scheduled for those times when significant features of the study area are most easily identified and differentiated. They are also useful for observing the general lay of the land, vegetation patterns and patch sizes, aquatic features, infrastructure, and disturbances within and around the site.

APPENDIX 3. NHI WORKING LIST AND KEY

The Wisconsin Natural Heritage Working List contains species known or suspected to be rare in the state and natural communities native to Wisconsin. It includes species legally designated as "Endangered" or "Threatened" as well as species in the advisory "Special Concern" category. Most of the species and natural communities on the list are actively tracked and we encourage data submissions on these species. This list is meant to be dynamic--it is updated as often as new information regarding the biological status of species becomes available. The Natural Heritage Program welcomes your input on any aspect of this list. Wisconsin's extirpated species list is at the end. Changes from the previous list (10/00) are bolded.

KEY

ELCODE: Unique 10 digit code for each element (plant, animal, or natural community).

Scientific Name: Scientific name used by the Wisconsin Natural Heritage Inventory Program.

Common Name: Standard, contrived, or agreed upon common names.

Global Rank: Global element rank. Refer to the Rank Definition Sheet.

State Rank: State element rank. Refer to the Rank Definition Sheet.

US Status: Federal protection status in Wisconsin, designated by the Office of Endangered Species, U.S. Fish and Wildlife Service through the U.S. Endangered Species Act. LE = listed endangered; LT = listed threatened; XN = non-essential experimental population(s); LT,PD = listed threatened, proposed for de-listing; C = candidate for future listing.

WI Status: Protection category designated by the Wisconsin DNR. END = endangered; THR = threatened; SC = Special Concern.

WDNR and federal regulations regarding Special Concern species range from full protection to no protection. The current categories and their respective level of protection are SC/P = fully protected; SC/N = no laws regulating use, possession, or harvesting; SC/H = take regulated by establishment of open closed seasons; SC/FL = federally protected as endangered or threatened, but not so designated by WDNR; SC/M = fully protected by federal and state laws under the Migratory Bird Act.

Special Concern species are those species about which some problem of abundance or distribution is suspected but not yet proved. The main purpose of this category is to focus attention on certain species before they become threatened or endangered.

GLOBAL & STATE ELEMENT RANK DEFINITIONS WISCONSIN NATURAL HERITAGE INVENTORY PROGRAM

GLOBAL ELEMENT RANKS:

G1 = Critically imperiled globally because of extreme rarity (5 or fewer occurrences or very few remaining individuals or acres) or because of some factor(s) making it especially vulnerable to extinction.

G2 = Imperiled globally because of rarity (6 to 20 occurrences or few remaining individuals or acres) or because of some factor(s) making it very vulnerable to extinction throughout its range.

G3 = Either very rare and local throughout its range or found locally (even abundantly at some of its locations) in a restricted range (e.g., a single state or physiographic region) or because of other factors making it vulnerable to extinction throughout its range; in terms of occurrences, in the range of 21 to 100.

G4 = Apparently globally secure, though it may be quite rare in parts of its range, especially at the periphery.

G5 = Demonstrably secure globally, though it may be quite rare in parts of its range, especially at the periphery.

GH = Of historical occurrence throughout its range, i.e., formerly part of the established biota, with the expectation that it may be rediscovered.

GU = Possibly in peril range-wide, but their status is uncertain. More information is needed.

GX = Believed to be extinct throughout its range (e.g. Passenger pigeon) with virtually no likelihood that it will be rediscovered.

G? = Not ranked.

Species with a questionable taxonomic assignment are given a "Q" after the global rank. Subspecies and varieties are given subranks composed of the letter "T" plus a number or letter. The definition of the second character of the subrank parallels that of the full global rank. (Examples: a rare subspecies of a rare species is ranked G1T1; a rare subspecies of a common species is ranked G5T1.)

STATE ELEMENT RANKS

S1 = Critically imperiled in Wisconsin because of extreme rarity (5 or fewer occurrences or very few remaining individuals or acres) or because of some factor(s) making it especially vulnerable to extirpation from the state.

S2 = Imperiled in Wisconsin because of rarity (6 to 20 occurrences or few remaining individuals or acres) or because of some factor(s) making it very vulnerable to extirpation from the state.

S3 = Rare or uncommon in Wisconsin (21 to 100 occurrences).

S4 = Apparently secure in Wisconsin, with many occurrences.

S5 = Demonstrably secure in Wisconsin and essentially ineradicable under present conditions.

SA = Accidental (occurring only once or a few times) or casual (occurring more regularly although not every year); a few of these species (typically long-distance migrants such as some birds and butterflies) may have even bred on one or more of the occasions when they were recorded.

SE = An exotic established in the state; may be native elsewhere in North America.

SH = Of historical occurrence in Wisconsin, perhaps having not been verified in the past 20 years, and suspected to be still extant. Naturally, an element would become SH without such a 20-year delay if the only known occurrence were destroyed or if it had been extensively and unsuccessfully looked for.

SN = Regularly occurring, usually migratory and typically non-breeding species for which no significant or effective habitat conservation measures can be taken in Wisconsin. This category includes migratory birds and bats that pass through twice a year or, may remain in the winter (or, in a few cases, the summer) along with certain lepidoptera which regularly migrate to Wisconsin where they reproduce, but then completely die out every year with no return migration. Species in this category are so widely and unreliably distributed during migration or in winter that no small set of sites could be set aside with the hope of significantly furthering their conservation.

SZ = Not of significant conservation concern in Wisconsin, invariably because there are no definable occurrences in the state, although the taxon is native and appears regularly in the state. An SZ rank will generally be used for long-distance migrants whose occurrence during their migrations are too irregular (in terms of repeated visitation to the same locations), transitory, and dispersed to be reliably identified, mapped, and protected. Typically, the SZ rank applies to a non-breeding population.

SR = Reported from Wisconsin, but without persuasive documentation which would provide a basis for either accepting or rejecting the report. Some of these are very recent discoveries for which the program hasn't yet received first-hand information; others are old, obscure reports that are hard to dismiss because the habitat is now destroyed.

SRF = Reported falsely (in error) from Wisconsin but this error is persisting in the literature.

SU = Possibly in peril in the state, but their status is uncertain. More information is needed.

SX = Apparently extirpated from the state.

STATE RANKING OF LONG-DISTANCE MIGRANT ANIMALS:

Ranking long distance aerial migrant animals presents special problems relating to the fact that their non-breeding status (rank) may be quite different from their breeding status, if any, in Wisconsin. In other words, the conservation needs of these taxa may vary between seasons. In order to present a less ambiguous picture of a migrant's status, it is necessary to specify whether the rank refers to the breeding (B) or non-breeding (N) status of the taxon in question. (e.g. S2B,S5N).

APPENDIX 4. ABBREVIATED LIST OF NHI NATURAL COMMUNITIES ASSOCIATED WITH THE NIAGARA ESCARPMENT

The Wisconsin Natural Heritage Inventory's recognized Natural Communities – Working Document. Prepared by Eric Epstein, Emmet Judziewicz and Elizabeth Spencer.

This document will be periodically updated and expanded. Future editions will include or be linked to additional descriptive information, range maps, and crosswalks to other vegetation classification systems.

Algific Talus Slope

This rare community of southwestern Wisconsin's Driftless Area consists of steep slopes of fractured limestone (dolomite) rock that retains ice and emits cold air throughout the growing season. The cold microhabitats enable the persistence of northern species and "periglacial relicts" such as northern monkshood (*Aconitum noveboracense*) and rare terrestrial snails. The woody overstory is often sparse, with scattered small black ash (*Fraxinus nigra*) and white birch (*Betula papyrifera*). Mountain maple (*Acer spicatum*), a northern shrub, may be frequent and extensive beds of bulblet fern (*Cystopteris bulbifera*) and mosses are characteristic.

Talus slope with a dense growth of *Cystopteris fragilis* beneath the escarpment. Peninsula State Park, June 25, 2000. Photo by Gary Fewless.

Alkaline Clay Bluff

Steep, clay bluffs occur along some stretches of the Great Lakes shorelines and less commonly inland on streams draining into Lake Superior and Lake Michigan. Vegetative cover ranges from forested with pines (*Pinus resinosa* and *P. strobus*), white cedar (*Thuja occidentalis*) and white birch (*Betula papyrifera*), to bare clay with only a few herbs present. Buffaloberry (*Sheperdia canadensis*) is a characteristic shrub, but more typically, alders (*Alnus incana* and *A. crispa*), as well as herbs such as Canada goldenrod (*Solidago canadensis*) and pearly everlasting (*Anaphalis margaritacea*) are prevalent. Both native and exotic pioneers such as fireweed (*Epilobium angustifolium*) and Canada thistle (*Cirsium arvense*) are common, especially on unstable sites. But it is the semi-stabilized "weeping" bluffs that are of the greatest biological interest. Golden sedge (*Carex aurea*), orchids and calciphilic fen species may colonize such sites, which can be local repositories of rare or otherwise noteworthy species.

Alvar

This rare community consists of areas of thin discontinuous soil overlying horizontal beds of limestone or dolomite in the vicinity of Great Lakes shorelines. They are characterized by

relatively low tree cover and a distinctive biota which includes elements of rock pavement, prairie, savanna and boreal forest communities. Among these are regional endemics, some very rare. Small coniferous and deciduous trees (cedar, fir, pine, oak, aspen, birch) are scattered among an assemblage of species that can include big bluestem (*Andropogon gerardii*), little bluestem (*Schizachyrium scoparium*), Indian-grass (*Sorghastrum nutans*), and wood lily (*Lilium philadelphicum*), as well as shoreline plants such as silverweed (*Potentilla anserina*) and dwarf lake iris (*Iris lacustris*).

Bedrock Shore

Wave-splashed bedrock shoreline ledges are best developed on sandstone in the Apostle Islands of Lake Superior. Stunted trees of white cedar (*Thuja occidentalis*), white birch (*Betula papyrifera*), showy mountain-ash (*Sorbus decora*) and green alder (*Alnus crispa*) are often present in crevices. Common herbs are ticklegrass (*Agrostis hyemalis*), fireweed (*Epilobium angustifolium*), and Canada goldenrod (*Solidago canadensis*), but the flora often includes unusual plants such as bird's-eye primrose (*Primula mistassinica*), brook lobelia (*Lobelia kalmii*), and three-toothed cinquefoil (*Potentilla tridentata*).

Boreal Forest

In Wisconsin, mature stands of this forest community are dominated by white spruce (*Picea glauca*) and balsam-fir (*Abies balsamea*), often mixed with white birch (*Betula papyrifera*), white cedar (*Thuja occidentalis*), white pine (*Pinus strobus*), balsam-poplar (*Populus balsamifera*) and quaking aspen (*Populus tremuloides*). Mountain-ash (*Sorbus* spp.) may also be present. Common understory herbs are large-leaved aster (*Aster macrophyllus*), bluebead lily (*Clintonia borealis*), Canada mayflower (*Maianthemum canadense*), wild sarsaparilla (*Aralia nudicaulis*), and bunchberry (*Cornus canadensis*). Most Wisconsin stands are associated with the Great Lakes, especially the clay plain of Lake Superior, and the eastern side of the northern Door Peninsula on Lake Michigan. Of potential interest from the perspectives of vegetation classification and restoration, white pine had the highest importance value of any tree in the Lake Superior region, as recorded during the original land survey of the mid-1800's.

Boreal Rich Fen

Neutral to alkaline cold open peatlands of northern Wisconsin through which carbonate-rich groundwater percolates. Sphagnum mosses are absent or of relatively minor importance, as calciphilic species (especially the "brown" mosses) predominate. Dominant/characteristic plants include woolly sedge (*Carex lasiocarpa*), twig rush (*Cladium mariscoides*), beaked bladderwort (*Utricularia cornuta*), rushes (*Juncus* spp.), and Hudson Bay cotton-grass (*Scirpus hudsonianus*). Shrubby phases also occur, with bog birch (*Betula pumila*), sage willow (*Salix candida*), and speckled alder (*Alnus incana*) present in significant amounts.

Braken Grassland

There is disagreement on whether bracken grassland should be considered a "natural community" in Wisconsin and elsewhere in the Upper Great Lakes region.

Calcareous Fen

An open wetland found in southern Wisconsin, often underlain by a calcareous substrate, through which carbonate-rich groundwater percolates. The flora is typically diverse, with many calciphiles. Common species are several sedges (*Carex sterilis* and *C. lanuginosa*), marsh fern (*Thelypteris palustris*), shrubby cinquefoil (*Potentilla fruticosa*), shrubby St. John's-wort (*Hypericum kalmianum*), Ohio goldenrod (*Solidago ohioensis*), grass-of-parnassus (*Parnassia glauca*), twig-rush (*Cladium mariscoides*), brook lobelia (*Lobelia kalmii*), boneset (*Eupatorium perfoliatum*), swamp thistle (*Cirsium muticum*), and asters (*Aster* spp.). Some fens have significant prairie or sedge meadow components, and intergrade with those communities.

Cedar Glade

Dry sandstone, quartzite or dolomite exposures vegetated with dense thickets of red cedar (*Juniperus virginiana*). Red maple (*Acer rubrum*), paper birch (*Betula papyrifera*) and black and bur oaks (*Quercus velutina* and *Q. macrocarpa*) may also be present. This community is usually if not always the result of fire suppression on dry prairies, and in pre-settlement times it may have occurred only where extensive cliffs served as firebreaks. Common herbs include bluestem and grama grasses (*Andropogon* spp. and *Bouteloua* spp.), prickly-pear cactus (*Opuntia compressa*), flowering spurge (*Euphorbia corollata*), stiff sandwort (*Arenaria stricta*), and gray goldenrod (*Solidago nemoralis*).

Dry Cliff

These dry vertical bedrock exposures occur on many different rock types, which may influence species composition. Scattered pines, oaks, or shrubs often occur. However, the most characteristic plants are often the ferns, common polypody (*Polypodium vulgare*) and rusty woodsia (*Woodsia ilvensis*), along with herbs such as columbine (*Aquilegia canadensis*), harebell (*Campanula rotundifolia*), pale corydalis (*Corydalis sempervirens*), juneberry (*Amelanchier* spp.), bush-honeysuckle (*Diervilla lonicera*), and rock spikemoss (*Selaginella rupestris*).

Dry Prairie

This grassland community occurs on dry, often loess-derived soils, usually on steep south or west facing slopes or at the summits of river bluffs with sandstone or dolomite near the surface. Short to medium-sized prairie grasses: little bluestem (*Schizachyrium scoparium*), side-oats grama (*Bouteloua curtipendula*), hairy grama (*B. hirsuta*), and prairie dropseed (*Sporobolus heterolepis*), are the dominants in this community. Common shrubs and forbs include lead plant (*Amorpha canescens*), silky aster (*Aster sericeus*), flowering spurge (*Euphorbia corollata*), purple prairie-clover (*Petalostemum purpureum*), cylindrical blazing-star (*Liatris cylindracea*), and gray goldenrod (*Solidago nemoralis*). Stands on gravelly knolls in the Kettle Moraine region of southeastern Wisconsin and along the St. Croix River on the Minnesota – Wisconsin border may warrant recognition, at least at the subtype level.

Emergent Aquatic

These open, marsh, lake, riverine and estuarine communities with permanent standing water are dominated by robust emergent macrophytes, in pure stands of single species or in various

mixtures. Dominants include cat-tails (*Typha* spp.), bulrushes (particularly *Scirpus acutus*, *S. fluviatilis*, and *S. validus*), bur-reeds (*Sparganium* spp.), giant reed (*Phragmites australis*), pickerel-weed (*Pontederia cordata*), water-plantains (*Alisma* spp.), arrowheads (*Sagittaria* spp.), and the larger species of spikerush such as (*Eleocharis smallii*).

Emergent Aquatic - Wild Rice

This open community is an emergent macrophyte type, with wild rice (*Zizania aquatica* or *Z. palustris*) as the dominant species. The substrate usually consists of poorly-consolidated, semi-organic sediments. Water fertility is low to moderate, and a slow current is present. Wild rice beds have great cultural significance to native peoples, and are important wildlife habitats.

Ephemeral Pond

These ponds are depressions with impeded drainage (usually in forest landscapes), that hold water for a period of time following snowmelt but typically dry out by mid-summer. Common aquatic plants of these habitats include yellow water crowfoot (*Ranunculus flabellaris*), mermaid weed (*Proserpinaca palustris*), Canada bluejoint grass (*Calamagrostis canadensis*), floating manna grass (*Glyceria septentrionalis*), spotted cowbane (*Cicuta maculata*), smartweeds (*Polygonum* spp.), orange jewelweed (*Impatiens capensis*), and sedges. Ephemeral ponds provide critical breeding habitat for certain invertebrates, as well as for many amphibians such as frogs and salamanders.

Felsenmeer

(Description in preparation)

Forested Ridge and Swale

This is a complex of semi- to fully-stabilized, often forested beach / dune ridges alternating with wet open to forested swales, found on the shores of the Great Lakes but best-developed along Lake Michigan. Both parallel the coast and offer exceptionally complex and diverse habitats for wetland, upland, and Great Lakes shoreline plants. Ridges may support assemblages similar to boreal, northern mesic, or northern dry-mesic forests. Water depth is a controlling factor in the swales, and the vegetation may run the gamut from open (emergent marsh, fen, or sedge meadow), shrub (bog birch, alder), or forested wetlands (often white cedar, black ash are prominent in these).

Forested Seep

These are shaded seepage areas with active spring discharges in (usually) hardwood forests that may host a number of uncommon to rare species. The overstory dominant is frequently black ash (*Fraxinus nigra*), but yellow birch (*Betula allegheniensis*), American elm (*Ulmus americana*) and many other tree species may be present including conifers such as hemlock (*Tsuga canadensis*) or white pine (*Pinus strobus*). Understory species include skunk cabbage (*Symplocarpus foetidus*), water-pennywort (*Hydrocotyle americana*), marsh blue violet (*Viola cucullata*), swamp saxifrage (*Saxifraga pennsylvanica*), golden saxifrage (*Chysosplenium americanum*), golden ragwort (*Senecio aureus*), silvery spleenwort (*Athyrium thelypteroides*)

and the rare sedges (*Carex scabrata* and *C. prasina*). Most documented occurrences are in the Driftless Area, or locally along major rivers flanked by steep bluffs.

Great Lakes Alkaline Rockshore

These are creviced, wave-splashed, nearly horizontal dolomite ledges along Lake Michigan on the Door Peninsula. Depending on lake levels, large expanses of this habitat may be either inundated or exposed during a given year. Common members of this community are the shrubs ninebark (*Physocarpus opulifolius*), shrubby cinquefoil (*Potentilla fruticosa*), and the herbs silverweed (*Potentilla anserina*), goldenrods (especially *Solidago hispida*), brook lobelia (*Lobelia kalmii*), gentians (*Gentiana* spp.), grasses-of Parnassus (*Parnassia* spp.), Indian paintbrush (*Castilleja coccinea*), low calamint (*Calamintha arkansana*), and many other calciphiles. Plants endemic to the Great Lakes shores are significant components of some stands.

Great Lakes Barrens

In Wisconsin, this variant of pine savanna is known from only one sandy site on Lake Superior. The dominant trees in this open stand are wind- and fire-deformed trees, red pines (*Pinus resinosa*) with white pine (*P. strobus*) also present. The understory consists of dense growths of lichens with scattered thickets of common juniper (*Juniperus communis*), early blueberry (*Vaccinium angustifolium*), and huckleberry (*Gaylussacia baccata*). Other common plants are hairgrass (*Deschampsia flexuosa*), ticklegrass (*Agrostis hyemalis*), false-heather (*Hudsonia tomentosa*), and bearberry (*Arctostaphylos uva-ursi*).

Great Lakes Beach

This beach community usually occurs in association with active dune systems. The beaches of the Great Lakes are extremely dynamic features, strongly influenced by water level changes and storm events. They support a suite of very specialized organisms, although unprotected shorelines may be entirely unvegetated. The plant species found in this community include (along Lake Michigan) seaside spurge (*Euphorbia polygonifolia*) and American sea-rocket (*Cakile edentula*).

Great Lakes Dune (formerly called Lake Dune)

The dominant plant in these semi-stabilized, open dunes along Great Lakes shorelines, is usually the sand-binding marram grass (*Ammophila breviligulata*). Frequent associates are common juniper (*Juniperus communis*), Canada wild-rye (*Elymus canadensis*), false-heather (*Hudsonia tomentosa*), beach-pea (*Lathyrus japonicus*), beach wormwood (*Artemisia campestris*), sand cherry (*Prunus pumila*), and various willows (*Salix* spp.). Two plants endemic to the Great Lakes region, pitcher's thistle (*Cirsium pitcheri*) and Lake Huron tansy (*Tanacetum huronense*; possibly now extirpated in Wisconsin), occur in this community along Lake Michigan.

Interdunal Wetland

Wind-created hollows that intersect the water table within active dune fields along the Great Lakes. These may be colonized by wetland plants, including habitat specialists that are of high conservation significance. Common members of this wetland community on Lake Superior are twig-rush (*Cladium mariscoides*), species of rushes (especially *Juncus balticus*), pipewort

(*Eriocaulon septangulare*), the sedge (*Carex viridula*), ladies-tress orchids (*Spiranthes* sp.) and bladderworts (*Utricularia cornuta* and *U. resupinata*).

Mesic Cedar Forest

This is a rare upland forest community of mesic sites in northern Wisconsin, characterized by white cedar (*Thuja occidentalis*) and various associates including hemlock (*Tsuga canadensis*), white spruce (*Abies balsamea*), yellow birch (*Betula alleghanensis*), and white pine (*Pinus strobus*). The herb layer may contain Canada mayflower (*Maianthemum canadense*), twinflower (*Linnaea borealis*), clubmosses (*Lycopodium* spp.), and others. More information is needed on this community type.

Moist Cliff

This "micro-community" occurs on shaded (by trees or the cliff itself because of aspect), moist to seeping mossy, vertical exposures of various rock types, most commonly sandstone and dolomite. Common species are columbine (*Aquilegia canadensis*), the fragile ferns (*Cystopteris bulbifera* and *C. fragilis*), wood ferns (*Dryopteris* spp.), rattlesnake-root (*Prenanthes alba*), and wild sarsaparilla (*Aralia nudicaulis*). The rare flora of these cliffs vary markedly in different parts of the state; Driftless Area cliffs might have northern monkshood (*Aconitum noveboracense*), those on Lake Superior, butterwort (*Pinguicula vulgaris*), or those in Door County, green spleenwort (*Asplenium viride*).

Northern Mesic Forest

This forest complex covered the largest acreage of any Wisconsin vegetation type prior to European settlement. Sugar maple (*Acer saccharum*) is dominant or co-dominant in most stands, while hemlock (*Tsuga canadensis*) was the second most important species, sometimes occurring in nearly pure stands with white pine (*Pinus strobus*). Beech (*Fagus grandifolia*) can be a co-dominant with sugar maple in the counties near Lake Michigan. Other important tree species were yellow birch (*Betula allegheniensis*), basswood (*Tilia americana*), and white ash (*Fraxinus americana*). The groundlayer varies from sparse and species poor (especially in hemlock stands) with woodferns (especially *Dryopteris intermedia*), bluebead lily (*Clintonia borealis*), clubmosses (*Lycopodium* spp.), and Canada mayflower (*Maianthemum canadense*) prevalent, to lush and species-rich with fine spring ephemeral displays. After old-growth stands were cut, trees such as quaking and bigtoothed aspens (*Populus tremuloides* and *P. grandidentata*), white birch (*Betula papyrifera*), and red maple (*Acer rubrum*) became and still are important in many second-growth Northern Mesic Forests. Several distinct associations within this complex warrant recognition as communities, and draft abstracts of these are currently undergoing review.

Northern Sedge Meadow

This open wetland community is dominated by sedges and grasses. There are several common subtypes: tussock meadows, dominated by tussock sedge (*Carex stricta*) and Canada bluejoint grass (*Calamagrostis canadensis*); broad-leaved sedge meadows, dominated by the robust sedges (*Carex lacustris* and/or *C. utriculata*); and wire-leaved sedge meadows, dominated by such species as woolly sedge (*Carex lasiocarpa*) and few-seeded sedge (*C. oligosperma*).

Frequent associates include marsh bluegrass (*Poa palustris*), manna grasses (*Glyceria* spp.), panicled aster (*Aster lanceolatus*), joy-pye-weed (*Eupatorium maculatum*), and the bulrushes (*Scirpus atrovirens* and *S. cyperinus*).

Northern Wet-Mesic Forest

This forested minerotrophic wetland is dominated by white cedar (*Thuja occidentalis*), and occurs on rich, neutral to alkaline substrates. Balsam fir (*Abies balsamea*), black ash (*Fraxinus nigra*), and spruces (*Picea glauca* and *P. mariana*) are among the many potential canopy associates. The understory is rich in sedges (such as *Carex disperma* and *C. trisperma*), orchids (e.g., *Platanthera obtusata* and *Listera cordata*), and wildflowers such as goldthread (*Coptis trifolia*), fringed polygala (*Polygala pauciflora*), and naked miterwort (*Mitella nuda*), and trailing sub-shrubs such as twinflower (*Linnaea borealis*) and creeping snowberry (*Gaultheria hispidula*). A number of rare plants occur more frequently in the cedar swamps than in any other habitat.

Oak Barrens

Black oak (*Quercus velutina*) is the dominant tree in this fire-adapted savanna community of xeric sites, but other oaks may also be present. Common understory species are lead plant (*Amorpha canescens*), black-eyed susan (*Rudbeckia hirta*), round-headed bush clover (*Lespedeza capitata*), goat's rue (*Tephrosia virginiana*), june grass (*Koeleria cristata*), little bluestem (*Schizachyrium scoparium*), flowering spurge (*Euphorbia corollata*), frostweed (*Helianthemum canadense*), false Solomon's-seals (*Smilacina racemosa* and *S. stellata*), spiderwort (*Tradescantia ohioensis*), and lupine (*Lupinus perennis*). Distribution of this community is mostly in southwestern, central and west central Wisconsin.

Oak Opening

As defined by Curtis, this is an oak-dominated savanna community in which there is less than 50% tree canopy. Historically, oak openings occurred on wet-mesic to dry sites. The few extant remnants are mostly on drier sites, with the mesic and wet-mesic openings almost totally destroyed by conversion to agricultural or residential uses, and by the encroachment of other woody plants due to fire suppression. Bur, white, and black oaks (*Quercus macrocarpa*, *Q. alba*, and *Q. velutina*) are dominant in mature stands as large, open-grown trees with distinctive limb architecture. Shagbark hickory (*Carya ovata*) is sometimes present. American hazelnut (*Corylus americana*) is a common shrub, and while the herb layer is similar to those found in oak forests and prairies, with many of the same grasses and forbs present, there are some plants and animals that reach their optimal abundance in the "openings".

Oak Woodland

This "forest" community is structurally intermediate between Oak Openings and Southern Dry Forest. The tree canopy cover is high, but frequent low-intensity fires and possibly (in pre-settlement times) browsing by herbivores such as elk, bison, and deer kept the understory relatively free of shrubs and saplings. Much additional information is needed but it appears that at least some plants (certain legumes, grasses, and composites among them) reached their highest abundance here.

Pine Barrens

This savanna community is characterized by scattered jack pines (*Pinus banksiana*), or less commonly red pines (*P. resinosa*), sometimes mixed with scrubby Hill's and bur oaks (*Quercus ellipsoidalis* and *Q. macrocarpa*), interspersed with openings in which shrubs such as hazelnuts, (*Corylus* spp.) and prairie willow (*Salix humilis*) and herbs dominate. The flora often contains species characteristic of "heaths" such as blueberries (*Vaccinium angustifolium* and *V. myrtilloides*), bearberry (*Arctostaphylos uva-ursi*), American hazelnut (*Corylus americana*), sweet fern (*Comptonia peregrina*), and sand cherry (*Prunus pensylvanica*). Also present are dry sand prairie species such as june grass (*Koeleria macrantha*), little bluestem (*Schizachyrium scoparium*), silky and sky-blue asters (*Aster sericeus* and *A. azureus*), lupine (*Lupinus perennis*), blazing-stars (*Liatris aspera* and *L. cylindracea*), and western sunflower (*Helianthus occidentalis*). Pines may be infrequent, even absent, in some stands in northern Wisconsin and elsewhere because of past logging, altered fire regimes, and an absence of seed source.

Shore Fen (formerly called Coastal Fen)

This open peatland community occurs primarily along Great Lakes shorelines, especially near the mouths of estuarine streams. Along Lake Superior most stands are separated from the lake waters by a sand spit. The floating sedge mat is composed mostly of woolly sedge (*Carex lasiocarpa*); co-dominants are sweet gale (*Myrica gale*) and bogbean (*Menyanthes trifoliata*). The following herbs are common in this diverse, circumneutral, nutrient-rich community: twigrush (*Cladium mariscoides*), marsh horsetail (*Equisetum fluviatile*), a spikerush (*Eleocharis elliptica*), intermediate bladderwort (*Utricularia intermedia*), marsh bellflower (*Campanula aparinoides*), narrow-leaved willow-herb (*Epilobium leptophyllum*), water-parsnip (*Sium suave*), and bog willow (*Salix pedicellaris*). Coastal fens are distinguished from open bogs and poor fens (which may adjoin them in the same wetland complex) by the lack of *Sphagnum* mosses, higher pH, and direct hydrologic connection to the Great Lakes. They are distinguished from rich fens by the absence of indicator species such as linear-leaved sundew (*Drosera linearis*), grass-of-parnassus (*Parnassia glauca*), false asphodel (*Tofieldia glutinosa*) and beaked spikerush (*Eleocharis rostellata*).

Southern Dry Forest

Oaks are the dominant species in this upland forest community of dry sites. White oak (*Quercus alba*) and black oak (*Quercus velutina*) are dominant, often with admixtures of red and bur oaks (*Q. rubra* and *Q. macrocarpa*) and black cherry (*Prunus serotina*). In the well developed shrub layer, brambles (*Rubus* spp.), gray dogwood (*Cornus racemosa*), and American hazelnut (*Corylus americana*) are common. Frequent herbaceous species are wild geranium (*Geranium maculatum*), false Solomon's-seal (*Smilacina racemosa*), hog-peanut (*Amphicarpaea bracteata*), and woodland sunflower (*Helianthus strumosus*).

Southern Dry-Mesic Forest

Red oak (*Quercus rubra*) is a common dominant tree of this upland forest community type. White oak (*Q. alba*), basswood (*Tilia americana*), sugar and red maples (*Acer saccharum* and *A. rubrum*), and white ash (*Fraxinus americana*) are also important. The herbaceous understory flora is diverse and includes many species listed under Southern Dry Forest plus jack-in-the-

pulpit (*Arisaema triphyllum*), enchanter's-nightshade (*Circaea lutetiana*), large-flowered bellwort (*Uvularia grandiflora*), interrupted fern (*Osmunda claytoniana*), lady fern (*Athyrium filix-femina*), tick-trefoils (*Desmodium glutinosum* and *D. nudiflorum*), and hog peanut (*Amphicarpaea bracteata*). To the detriment of the oaks, mesophytic tree species are becoming increasingly important under current management practices and fire suppression policies.

Southern Hardwood Swamp (A split from Curtis' Southern Wet-Mesic Forest)

This is a deciduous forested wetland community type found in insular basins with seasonally high water tables. It is best developed in glaciated southeastern Wisconsin. The dominant trees are red maple (*Acer rubrum*), green ash (*Fraxinus pennsylvanica*), and formerly, American elm (*Ulmus americana*). The exotic reed canary grass (*Phalaris arundinacea*) is often dominant in the understory. This Natural Heritage Inventory community partly includes the Southern Wet-Mesic Forest of the Curtis classification.

Southern Mesic Forest

This upland forest community occurs on rich, well-drained soils. The dominant tree species is sugar maple (*Acer saccharum*), but basswood (*Tilia americana*) and (near Lake Michigan) beech (*Fagus grandifolia*) may be co-dominant. Many other trees are found in these forests, including those of the walnut family (Juglandaceae). The understory is typically open (sometimes brushy with species of gooseberry (*Ribes*) if there is a past history of grazing) and supports fine spring ephemeral displays. Characteristic herbs are spring-beauty (*Claytonia virginica*), trout-lilies (*Erythronium* spp.), trilliums (*Trillium* spp.), violets (*Viola* spp.), bloodroot (*Sanguinaria canadensis*), blue cohosh (*Caulophyllum thalictroides*), mayapple (*Podophyllum peltatum*), and Virginia waterleaf (*Hydrophyllum virginianum*).

Southern Sedge Meadow

Widespread in southern Wisconsin, this open wetland community is most typically dominated by tussock sedge (*Carex stricta*) and Canada bluejoint grass (*Calamagrostis canadensis*). Common associates are water-horehound (*Lycopus uniflorus*), paniced aster (*Aster simplex*), blue flag (*Iris virginica*), Canada goldenrod (*Solidago canadensis*), spotted joe-pye-weed (*Eupatorium maculatum*), broad-leaved cat-tail (*Typha latifolia*), and swamp milkweed (*Asclepias incarnata*). Reed canary grass (*Phalaris arundinacea*) may be dominant in grazed and/or ditched stands. Ditched stands can succeed quickly to Shrub-Carr.

Submergent Aquatic

This herbaceous community of aquatic macrophytes occurs in lakes, ponds, and rivers. Submergent macrophytes often occur in deeper water than emergents, but there is considerable overlap. Dominants include various species of pondweeds (*Potamogeton* spp.) along with waterweed (*Elodea canadensis*), slender naiad (*Najas flexilis*), eel-grass (*Vallisneria americana*), and species of water-milfoil (*Myriophyllum*) and bladderworts (*Utricularia*).

Talus Forest (Description in preparation)
