**DNR CERTIFICATION**

I have reviewed this guidance document or proposed guidance document and I certify that it complies with sections 227.10 and 227.11 of the Wisconsin Statutes. I further certify that the guidance document or proposed guidance document contains no standard, requirement, or threshold that is not explicitly required or explicitly permitted by a statute or a rule that has been lawfully promulgated. I further certify that the guidance document or proposed guidance document contains no standard, requirement, or threshold that is more restrictive than a standard, requirement, or threshold contained in the Wisconsin Statutes.

Signature: [Signature]
Date: October 16, 2019
DNR GUIDANCE DISCLAIMER

This document is intended solely as guidance and does not contain any mandatory requirements except where requirements found in statute or administrative rule are referenced. Any regulatory decisions made by the Department of Natural Resources in any matter addressed by this guidance will be made by applying the governing statutes and administrative rules to the relevant facts.
In order to use certain exemptions from air pollution operation or construction permits, a facility’s Maximum Theoretical Emissions (MTE) must be calculated. For more details on the different air permit exemption options, go to the Air Permit Exemptions web page:  http://dnr.wi.gov/topic/smallbusiness/exemptions.html.

What Does Maximum Theoretical Emissions (MTE) Mean?

There are two different definitions for MTE in the air pollution rules in the Wisconsin Administrative Code. This fact sheet will address the definition of MTE in s. NR 400.02(95), Wis. Adm. Code:

“[...] means the quantity of air contaminants that theoretically could be emitted by a stationary source without control devices based on the design capacity or maximum production capacity of the source. When determining annual maximum theoretical emissions, a source shall be presumed to operate 8,760 hours per year unless its physical design precludes 8,760 hours of operation per year. Where a source’s physical design restricts the number of hours it may operate, annual maximum theoretical emissions shall be calculated taking this restriction into account. In determining the maximum theoretical emissions of VOCs [Volatile Organic Compounds] for a source, the design capacity or maximum production capacity shall include the use of raw materials, coatings and inks with the highest VOC content used in practice by the source. In determining the maximum theoretical emissions of a hazardous air contaminant for a source, the design capacity or maximum production capacity shall include the use of raw materials, coatings, inks and fuels with the highest hazardous air contaminant content used in practice by the source. Realistic operating conditions shall be taken into account in determining emissions under this subsection.”

There are important aspects to the MTE definition facilities should review carefully. MTE allows for design elements that limit a facility from operating a full 8,760 hours or “realistic operating conditions” that otherwise restrict emissions. MTE is also calculated as if the raw material with the highest air pollutant content available to the source were used all the time.

The annual MTE is important for determining which type of permit is appropriate. However, the hourly MTE is used to show whether a facility is exempt from either construction or operation permit requirements. A facility can use realistic operating conditions to determine hourly MTE the conditions truly limit the operations on an hour-by-hour basis. Operating conditions that only affect or limit operations over longer periods of time (i.e., a facility must shut down machinery for maintenance once every three months for a full week) cannot be used to determine the hourly MTE, only the annual MTE.

Volatile Organic Compounds (VOC)

Volatile organic compounds (VOCs) are found in many operations; often coming from painting, solvent cleaning or combustion of a fuel in a boiler or oven. For a facility operating a paint spray booth, the MTE are calculated based on operating the spray gun at full open and using the coating with the highest VOC content that could be sprayed or applied continuously for 24 hours per day, 365 days per year (8,760 hours per year). The VOC content of a coating is found on Safety Data Sheets (SDS) provided by the manufacturer or supplier.
If the highest VOC content coating has 5.60 pounds VOC per gallon and, at full open, the gun can spray 14 gallons per hour, the MTE for that paint spray booth would be calculated as:

14 gal/hr x 5.6 lb VOC/gal = 78.4 lbs VOC/hr
78.4 lb/hr x 8760 hr/yr ÷ 2000 lb/ton = 343.4 tons VOC/year

If the facility used a coating with low VOC content—in this example, 2.4 lbs VOC/gal— the emissions would be:

14 gal/hr x 2.4 lb VOC/gal = 33.6 lbs VOC/hr
33.6 lb/hr x 8760 hr/yr ÷ 2000 lb/ton = 147.2 tons VOC/year

Some processes do not have clearly defined maximum production capacities or design capacities. In those cases, MTE can be projected from actual VOC emissions based on the MTE of associated processes that do have defined maximum production capacities or design capacities. Using an example of cleaning operations on a coating line, one can estimate the MTE by looking at a maximum production or design capacity operating scenario for the coating line and using other available information, including production and maintenance records, to establish the cleaning operations worst case schedule.

For example, assume that one production cycle (seven hours of production and one hour of cleaning) occurs daily and the production area is cleaned after each production cycle. However, if three production cycles (21 hours of production and three hours of cleaning) could be completed daily under a maximum production scenario, one can assume three times the quantity of cleaning materials would be required daily. This would triple the actual emissions from cleaning materials. However, if actual production records indicate that cleaning is necessary only after every other production cycle, this practice would be taken into account in the MTE calculation. For an example of this type of calculation, refer to the VOC Emissions tab on the MTE spreadsheet:

Calculating the total MTE of VOCs for a facility requires this type of calculation for every process that emits VOCs, for both the hourly and annual MTE. The facility-wide MTE of each pollutant is the sum total of the MTE from all processes at the facility that have emissions of that pollutant.

Realistic operating conditions that can be taken into account for MTE do not include operation of a control device or permit restrictions taken to limit the annual operations at the source (such as hours per year or gallons per year). Only conditions specific to the design of the operations can be considered. For a construction permit, it could be difficult to account for these conditions, since no operational track record exists for a new process.

Examples of operating conditions that could restrict MTE include:

- If a process line must be taken off-line for two weeks of every year for regular maintenance, then it can only operate 8424 hours per year.
Air Program Fact Sheet • MTE Calculations for Air Permit Exemptions

14 gal/hr x 5.6 lb VOC/gal x 8424 hr/yr ÷ 2000 lb/ton = 330.2 tons VOC/year

♦ A painting operation applies paint to very large parts, and only one part can be painted per hour because it also must dry within the paint booth. The hourly paint spray rate is limited to the gun operating at full open for the time it takes to paint the largest part during that hour. For this example, if paint is applied for no more than 15 minutes in any hour:

1) (14 gal/hr x 0.25 hr) + (0 gal/hr x 0.75 hr) ÷ 1 hr = 3.5 gal/hr
2) 3.5 gal/hr x 5.6 lb VOC/gal x 8760 hr/yr ÷ 2000 lb/ton = 85.8 tons VOC/year

Conditions used to determine MTE must be documented to show Department of Natural Resources (DNR) and U.S. Environmental Protection Agency (EPA) that they cannot be altered or changed in any way without requiring a construction permit.

Certain control measures may be used to determine MTE if they are not used solely for reducing air pollution. In Wisconsin, DNR defines this scenario as control devices that are “part of the process.” For example, a whey drying process uses a fabric filter baghouse to capture dried whey. The baghouse reduces the particulate matter emissions, but more importantly is the primary way in which the facility collects their final product and moves it to the bagging and shipping stage of production.

Contact the facility’s assigned DNR compliance inspector to ask if a scenario will meet the criteria. Decisions are made on a case-by-case basis to establish whether the control is truly part of the process. If a facility has received a determination from the DNR in the past, be sure to have on file any records needed to demonstrate the criteria used in that scenario continue to apply.

Sulfur Dioxide (SO₂)

For some fuels, the calculation of SO₂ MTE is not simply a matter of multiplying a unit of material used by an emission factor. Fuels such as fuel oil or coal will have a sulfur content in percent by weight that must be used in the calculation of MTE.

Starting in 1993 fuel oil with 5000 ppm (0.5% sulfur) was no longer allowed in any vehicles. As of 2006, on-road diesel fuel could no longer be sold with more than 15 ppm (or 0.0015% by weight) sulfur content; however, off-road vehicles could still use 500 ppm (0.05% sulfur). While both low-sulfur diesel and ultra-low sulfur diesel are allowed in the appropriate circumstances, most suppliers do not carry fuel oil with multiple levels of sulfur content; requiring multiple storage tanks.

Therefore, permits using the old assumption of a worst case sulfur content at 0.5% by weight are no longer correct. At most, the worst case assumption of 0.05% sulfur should be used to calculate SO₂ MTE. Some generator engines are required by the federal NESHAP/NSPS to use the ultra-low sulfur diesel at 0.0015% sulfur. When required by rule, this sulfur content should be used for MTE calculations.

Sulfur dioxide EF (lb/1000 gal) = 142 * % S = 142 * (0.05) = 7.1 lb/1000 gal or lb/gal³

$\text{MTE (lb/hr)} = \frac{\text{Boiler maximum heat input rating (mmBTU/hr)} \times \text{EF (lb/gal³)}}{140 \text{ mmBTU/gal³}}$

$\text{MTE (TPY)} = \text{MTE (lb/hr)} \times 8760 \text{ hr/yr} \div 2000 \text{ lb/ton}$
Biogas SO₂

Many facilities are using biogas, which adds complexity to the SO₂ MTE calculation. First, the concentration of hydrogen sulfide (H₂S) in the biogas is needed.

\[
\text{Concentration of H}_2\text{S in mg/m}^3 = (500 \text{ ppm}) \times \left(\frac{34 \text{ molecular weight of H}_2\text{S}}{24.45}\right) = 695 \text{ mg/m}^3
\]

\[
\text{Gas flow rate convert to m}^3/\text{hr} = (5,880 \text{ scfh}) \times \left(\frac{1 \text{ m}^3}{35.28 \text{ ft}^3}\right) = 166.7 \text{ m}^3/\text{hr}
\]

\[
\text{Mass of H}_2\text{S} = \text{Concentration} \times \text{Flow} = (695 \text{ mg/m}^3) \times (166.7 \text{ m}^3/\text{hr}) \times (1/1000) \times (1 \text{ lb/454 g}) = 0.26 \text{ lb/hr H}_2\text{S}
\]

\[
\text{Convert H}_2\text{S to SO}_2 = (0.26 \text{ lb/hr H}_2\text{S}) \times \left(\frac{64 \text{ molecular weight of SO}_2}{34 \text{ molecular weight of H}_2\text{S}}\right) = 0.49 \text{ lb/hr SO}_2
\]

\[
\text{MTE SO}_2 \text{ in TPY} = (0.49 \text{ lb/hr SO}_2) \times (8760 \text{ hr/year}) \times (1 \text{ ton/2000 lb}) = 2.14 \text{ TPY SO}_2
\]

**Assumptions**

- Calculations based on potential of 500 parts per million (ppm) H₂S in biogas
- Reaction when H₂S is combusted: \(2 \text{ H}_2\text{S} + 3 \text{ O}_2 \rightarrow 2 \text{ SO}_2 + 2 \text{ H}_2\text{O}\)
- Constant of 24.45 in the equation is the volume in liters of a mole (gram molecular weight) of a gas or vapor when the pressure is at 1 atmosphere and at 25°C
- Fuel consumption in standard cubic feet/hour (scfh) at 100% load per engine specifications is needed for the calculation (use 5880 scfh for this example)
- Conservative calculation as it assumes enough gas is available to run the engine 8,760 hours per year

It is important to note that each source of biogas will have different concentrations of H₂S and the fuel consumption flow rate will change for each engine. Those values should be adjusted for each situation.

**Engines**

Each engine will require its own set of emissions calculations based on the size of the engine, the fuel type used and any limit on hours of operation. Emergency engines that meet the definition of emergency stationary reciprocating internal combustion engine (RICE) or black start engine in 40 CFR 63.6675 or that meet the definition of limited use RICE in 40 CFR 63.6675 can assume a 500 hr/yr operation to determine their MTE. All other non-emergency engines must use 8760 hr/yr to determine MTE unless operation hours are limited in a permit.

**Fugitive Emissions**

There is often confusion about when fugitive emissions must be included to determine permit applicability. For the MTE-based permit exemption, use the definition of a “major source” to determine when fugitive emissions should be included:

> The fugitive emissions of a stationary source may not be considered in determining whether it is a major source for the purposes of this definition, unless the source belongs to one of the following categories of stationary sources: [...]"
That means fugitive emissions are not included in MTE calculations unless a source is one of the 27 categories listed in s. NR 407.02(4)(b), Wis. Adm. Code. "Fugitive emissions" are defined as those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening in s. NR 407.02(3e). Examples of fugitive emissions include those from truck traffic on haul roads, loading and unloading to outdoor storage piles, and other dust from outdoor storage piles. Indoor uncaptured emissions that are not vented outside the building are a different situation and should be discussed with DNR staff if you have questions whether certain emissions should be considered “fugitive emissions” for MTE calculations.

Fugitive emissions are always included for purposes of reporting emissions under ch. NR 438.

**Demonstrating Use of an Exemption**

In the event a facility wishes to use the MTE calculations to demonstrate they meet certain exemptions, it is best to review the eligibility requirements for those exemptions. The Small Business Environmental Assistance Program (SBEAP) recommends reviewing the Exemptions web page for more information. Go to [http://dnr.wi.gov/topic/smallbusiness/](http://dnr.wi.gov/topic/smallbusiness/) and scroll down to the box for Air and select the “Exemptions” link. Each exemption option tab describes the process for submitting a request to DNR.

When requesting use of one of the exemptions, calculations for each criteria pollutant, and hazardous air pollutant(s) if needed, should be provided to DNR for their review. A spreadsheet containing example MTE calculations for a wide range of operations is available here: [http://dnr.wi.gov/topic/SmallBusiness/documents/air/EmissionsWorksheetMTE.xlsx](http://dnr.wi.gov/topic/SmallBusiness/documents/air/EmissionsWorksheetMTE.xlsx). If an example is not provided that fits a particular situation, contact the SBEAP staff at 1-855-889-3021 or [DNRSmallBusiness@wisconsin.gov](mailto:DNRSmallBusiness@wisconsin.gov).

**Contact for Additional Information**

If there are additional questions on the use of MTE in an exemption request that this information did not address, contact the **Air Permit Exemption Coordinator** at 608-266-7718.
