Introduction

The Department of Natural Resources Fisheries Management staff conduct annual monitoring of trout populations at 43 locations distributed throughout 17 watersheds in Southwest Wisconsin. These surveys allow for the tracking and evaluation of changes in trout population abundance and size structure through time.

The following data is displayed as the number of trout collected per mile of electrofishing. Each line on the graph represents a different length category, so >8 inches indicates all trout above 8 inches that were captured. Each chart also includes typical catch rates for the entire Driftless region (shown as the median value for each length class) for each species. These values are shown to the right of each chart, and as dotted horizontal lines. In some cases, the lines may not be visible within the range of catch rates on the chart. The following slide indicates how to interpret each chart.

Because a trout's length corresponds to its age early in life, we can also use this data to estimate year class strength of age 0 and age 1 trout. The difference between the all trout value and trout greater than 4 inches value is the amount of age 0 trout. The difference between the trout greater than 4 inches and the trout greater than 8 inches (7 inches for brook trout) is the amount of age 1 trout. At age 2 the growth slows, and length alone cannot be used to infer age.

Having trend sites spread throughout the watersheds allows us to detect regional trends that can help explain variation that may be driven by climate and weather. Stream temperature and stream discharge (flow) are also measured at these locations to help explain variation and trends.
Species

How the stream/site compares with other regional streams/sites

Connected lines mean surveys were conducted in consecutive years
